Alliance Year Book for 1916, 533
ALZHEIMER, Dr., death of, 506
Ambulance motor, development of (H. Massac Buiet), 18
Ambulance organization in Austria, faulty (Einar Aaser), 65
Ambulance train at Aberdeen, Red Cross, 867

America. *See* United States
American Journal of Orthopaedic Surgery, 183
Amoebae in urine in a case of infectious jaundice (H. B. Fantham), 553
Amoebic dysentery. *See* Dysentery
Amoss: Chemical treatment of cerebro-spinal fever, 763
Amputation, indications for (Albrecht), 355
Amputations and amputation stamps, War Office memorandum, 534—Correspondence on, 836
Amputations at base hospitals in France (C. Gordon Watson), 479. (O)
Amputation stumps, after-treatment of (C. W. G. Bryan), 480. (O)
Anaemia, pernicious (O. Leyton), 784. (O)—Correspondence on, 570
Anaemia, pernicious, and erythraemia, 570
Anaemia, tropical. *See* Uncinariasis
Anaerobic culture, simple method of (Dr. Beattie), 569, 756. (O)
Anaesthesia, local, by quinine and urea hydrochloride solution, 640
Anaesthesia, sudden heart failure under, direct massage of heart, recovery (Gerald Sichel), 201
Anaesthetics administered by unqualified persons, 425
Anaesthetics, influence of on the body temperature (M. S. Pembrey and F. E. Shipway), 655
Anaesthetics, review of books on, 622
ANASTASSION, N.: *Greek Self-taught (Modern), with Phonetic Pronunciation (Thimm's System)*, rev., 692
Anatomy, review of books on, 203
ANDERSON, F. T.: Introduction of cinchona trees into India, 324
ANDERSON, G. H., obituary notice of, 575
ANDERSON, James, obituary notice of, 775
ANDREWS, F. W.: Bacteriology of cerebro-spinal fever, 689
ANDREWS, H. R.: Appreciation of R. Drummond Maxwell, 434
Aneurysm, arterio-venous, of the subclavian artery and vein (Comyns Berkeley and Victor Bonney), 753. (O)
Aneurysm, traumatic, case of marked temporary aphasia after ligation of the common carotid artery for (Frank Cole Madden), 585. (O)
ANGULUS, Ludovici, 260, 296
ANICOT, Dr., killed at his post, 808
Animals, living, chlorine gas for (parliamentary question), 25
ANDERSON, Captain J. W., Military Cross conferred upon, 146
Ankle, splint for compound fracture (Major M. Sinclair), 197. (O)
Ankylosis following gunshot injuries of positions of election for (Lieut.-Col. Jones), 609. (O)
Anodyne powder, 608
Antenatal clinics and prematers at the Edinburgh Royal Mater in the years 1909-1915 (J. W. Be), 234, 275. (O)

- Anthropology, review of books on, 376
 Antimony in kala-azar. *See* Kala-azar
 Antiseptic, brilliant green as an (Archibald Leitch), 236. (O)
 Antiseptic, a new intestinal (J. T. Ainslie Walker), 311
 Antiseptics, influence of on the activities of leucocytes and on the healing of wounds (C. J. Bond), 777. (O)
 Antiseptics, studies in: II, Chloramine (H. D. Dakin, J. B. Cohen, and J. Kenyon), 160. (O) —Note on, 388
 Antitetanic serum, two cases of tetanus treated successfully by subdural injections of (N. W. Mackworth), 620
 Antitetanic serum, value of (J. Crawford Renton), 89. *See also* Tetanus
 Antitoxin, free, in Ontario, 632
 Antitoxin treatment of tetanus. *See* Tetanus
 Antityphoid inoculation: French army results in (Jules Courmont), 27—Parliamentary questions on, 105, 533, 829—In the Russian army, 775—Research Defence Society's leaflet, 147
 Aorta, compression of in post-partum haemorrhage (C. Stennett Redmond), 15
 Aphasia, marked temporary, after ligation of the common carotid artery for traumatic aneurysm (Frank Cole Madden), 585. (O)
 Apothecaries' Hall of Ireland, 399
 Apothecaries' Society of London, degrees and pass lists, 35, 116, 186, 362, 505, 571, 635, 774

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, JANUARY 1st, 1916.

Remarks

ON THE

GENERAL TREATMENT OF INFECTED "GUNSHOT WOUNDS"

FROM A CLINICAL POINT OF VIEW.*

BY

COLONEL H. M. W. GRAY, A.M.S.(T.),

CONSULTING SURGEON, BRITISH EXPEDITIONARY FORCE, FRANCE.

WE have been compelled, since this war began, to acknowledge the inefficiency of antiseptics when used as preventive or disinfecting agents in badly infected, lacerated wounds. Until applications were employed which stimulated a concentration of the general defensive forces of the body in and around the wound, no real advance in treatment was made. It mattered not what kind or what strength of antiseptic, pure and simple, was used, the infection ran a fairly definite course of fairly definite duration, which varied merely according to the patient's power of resistance. While the importance of free drainage was very speedily acknowledged, quite a long time passed before there was any satisfactory recognition of the fact that the resisting agencies of the patient's own body are far more effective in dealing with a local infection than any purely antiseptic solution, powder, or paste introduced into it from without.

Too great credit cannot be given to Colonel Sir Almroth Wright for his work in connexion with this matter. It must be gratifying to him that his laboratory experiments have now been so fully confirmed by clinical experience. There is no need to discuss the merit of his work; it suffices to say that the principles of treatment which he has laid down govern, very largely, the methods now in use in the British hospitals at Rouen.

The tissues implicated in a severe wound are more or less devitalized by the severity of the trauma, and are thus rendered more vulnerable to the onslaught of microbes. This is seen in the slow healing of insignificant skin wounds caused by a bullet, even though they are only very mildly infected. The temporary functional inhibition induced by the injury is probably aggravated and prolonged when ordinary antiseptics are used in large wounds. Organisms which have invaded the tissues are not killed by the action of antiseptics as such unless they are in a layer of tissue directly affected by an antiseptic sufficiently strong to destroy it. Antiseptic applications can affect practically only those organisms which are actually in the cavity of the wound, but they can prevent fresh infection and the spread of infection from one case to another; their use for these purposes should never be omitted. What has to be aimed at, however, is to support and stimulate the forces of defence which the patient himself can bring to bear on the invading organisms, by both local and general means. There is ample evidence, obtainable daily in the wards of a large hospital, that the new principle which guides the treatment of seriously infected wounds is of far greater importance than that involved in the use of antiseptics as hitherto applied. All

successful treatments of infected wounds depend on calling forth these physiological forces, these protective elements of the body, whether fluid or cellular, or both. It has been proved to the satisfaction of the large number of surgeons working in my area that the use of salt solutions, applied in various ways, fulfils all the striking claims made for it by Sir Almroth Wright.

The addition of antiseptics to the salt solution is not yet proved to be of any advantage to the wound once it has become seriously infected. Cases treated by hypertonic salines alone compare most favourably with similar cases treated even by those antiseptic solutions most recently advocated, as, for example, those cases of gas gangrene recorded by Captain John Fraser¹ treated by hypochlorous acid, or eusol solution. A few of our surgeons add eusol to the salt solution, as they consider that it removes the bad odour of wounds more quickly and hastens the separation of sloughs. After observing a very large number of cases, I am inclined to agree with others who are not convinced regarding these effects. Their attitude towards eusol is expressed in the remark—"It does no harm." In virtue of its having hypertonic and deodorizing effects, eusol acts well when used for continuous irrigation or baths. It seems to do well also in some cases of *pyocyaneus* infection. But it does not deserve to supplant salt treatment.

Judging from what has been written about the hypochlorite treatment, especially by Dr. Alexis Carrel, it is not unlikely that it may be adopted widely before the possible drawbacks to its general use are appreciated. It may prove eminently successful in aborting infection in wounds which can be treated early, before micro-organisms have penetrated into the tissues, but its use for such a purpose apparently demands great attention to detail, both at the primary operation and during the succeeding days, before the wound can be pronounced free from microbes. It thus calls for the expenditure of more time and for a greater number of attendants than are usually available, even if the patients could be put under the treatment early enough. The treatment cannot be carried out during transport of a large number of cases, and is, on that account especially, unsuitable during a "rush." After the recent severe fighting (September 25th and following days), when the hypochlorite treatment was being used at many of the casualty clearing stations, the condition of severe deep wounds arriving in Rouen was no better than had been that of those arriving from fights earlier in the campaign—for example, from Neuve Chapelle or Hill 60.

For routine and general use under such conditions as exist on the British front and lines of communication in France it is requisite that some dressing should be available which is effective in preventing severe sepsis, easy to carry, simple in application, economical of material and time, and so continuous in action that little attention is necessary during transport. Hypertonic saline dressing, especially in the form now known as the "tablet and gauze pack," fulfils these desiderata better than any other yet applied. As Colonel C. B. Lawson has said, "many wounds treated in this way arrive in such excellent condition that during a rush the men can be transferred directly to England, without more interference than adjusting the superficial dressings. The patients' temperatures are normal and the wounds are free from surrounding inflammation." The method of using the "tablet and gauze pack" will be described later, but it may here be pointed out that the slow dissolution of the tablets in the

* Read before the Rouen Medical Society (B.A.M.C. Officers) on November 27th, 1915.

folds of gauze, which sometimes occupies many days, provides a continuous supply of hypertonic solution until they are completely dissolved.

SOME GENERAL CONSIDERATIONS GOVERNING THE USE OF SALT SOLUTIONS.

Attention must be drawn to certain important factors which have a very direct bearing on the successful application of simple solutions of salt.

1. The solution must be brought into contact with every infected part of the wound.

2. Hypertonic solutions stimulate a more or less profuse flow of lymph containing antibodies, and thus bring about what has been called "lymph lavage" of the tissues lining the wound.

3. Isotonic or physiological salt solution stimulates diapedesis—that is to say, it brings about a concentration of leucocytes in these tissues. These phagocytes are in large measure shed into the wound cavity and form pus corpuscles.

4. The micro-organisms causing the infection make their way into the tissues lining the wound in a few hours. The rapidity and depth of penetration vary according to the kind of organism, the amount of devitalization of the tissues, and the method of treatment.

5. The infective material is carried by the missile into the depths of the wound; any superficial treatment is therefore of no practical benefit, except in preventing fresh infection.

6. The presence of effused fluids, whether blood or lymph, of foreign bodies, and of badly lacerated or necrotic tissues, favours the rapid growth of organisms in the wound and hinders their expulsion from it.

7. Wounds deteriorate in condition, inflammation may become rampant, especially during transport; if the wounded part be not properly fixed and supported, even although no fracture be present.

8. A patient whose vitality is very low owing to the severity both of the wound and of the sepsis is unlikely to fight serious infection successfully and to survive a conservative operation and the strain which after-treatment involves. The question of amputation must therefore occupy a far more prominent place in the mind of the surgeon than it does in civil practice.

9. The method of treatment must therefore vary according to the nature of the chief infecting organisms, the physical character of the wound, the general condition of the patient, and according to whether he is to be transported or not within a short time.

Bacteriological Indications.

Although the clinical characters of the wounded part often give quite reliable indications of the important bacteriological contents, yet a report from the laboratory on the kind of organisms present may be of the greatest service. For example, the streptococcus thrives in lymph, but finds in the phagocyte a very deadly enemy. Therefore, when it is found that streptococci are making headway in a wound, or are found in pure culture in a joint, isotonic solutions should be used for treatment of the wound or washing out the joint.

In ordinary deep wounds, however, and especially in the early stages when multiple infection is likely to be present, hypertonic applications are best.

OPERATIVE TREATMENT.

Free incision or excision of the superficial parts of the wound, including especially the deep fascia, is practically essential to success, in order to make it possible to cleanse and drain thoroughly and to insert the "tablet and gauze pack" properly. Exposed aponeurotic structures are certain to slough, hence they should be cut away. At the beginning of the war there existed a great antipathy in many quarters to making fresh incisions in the presence of acute and even of chronic sepsis, because it was thought that such incisions, by laying bare fresh tissue, entailed a greater risk from the spread of infection than the simple insertion of a large drainage tube through a smaller opening. When suitable saline treatment is used it is found that there is no such increase of danger; quite the reverse. The success of the open method of treating amputation stumps amply demonstrates the truth of this.

Transverse or oblique incisions admirably fulfil their purpose and are sometimes compulsory, yet one must remember that only rarely can a muscle which has been cut completely across be united again satisfactorily. Transverse incisions, therefore, are apt to be mutilating and harmful to function afterwards. A smaller cone-shaped excision, in which part only of the muscle is sacrificed, sometimes gives even more efficient drainage. It must be remembered that occasionally the whole belly of a muscle is virulently infected. When that happens the muscle will necrose, and it is far quicker and safer to excise the whole muscle at once—for example, the rectus femoris or gluteus maximus. In any case it is best to insert a finger in the wound and examine its extent and arrangement before deciding what form of incision or excision is to be employed.

Counter-openings at the most dependent parts of the cavity are of great importance in certain cases.

Cleansing of the Wound.—Extraordinary divergence of opinion exists as to what constitutes thorough cleansing of the wound. Mere blind twisting of a swab inside a wound cavity may do as much harm as good. Simple flushing through with a solution is very ineffectual, and if hydrogen peroxide be used infective particles may be carried into recesses of the wound which were previously clean. A lacerated deep wound should be thoroughly opened up and every pocket of it examined and enlarged if necessary. Meticulous care should be exercised in removing foreign bodies and blood clot by forceps, fingers, or swab, and clipping away all necrotic or badly lacerated muscle or fibrous tissue. Irrigation is rarely necessary or desirable. Each pocket must then be carefully packed in the manner described later. If any recess be left untreated, there is great risk that the wound will not do well.

Fixation of the wounded part must be secured, in mild cases by proper bandaging, in severe cases by splints, even although the soft parts only are affected. Efficient fixation will limit effusion and consequent swelling, as well as the amount of pain which the patient will suffer.

Support.—The soft parts must be prevented from sagging, especially when deep lacerated wounds accompany fractures of such a bone as the femur. Support is best provided in such a case by suitably shaped "gutters" of sterilized perforated zinc, which are placed under the limb. The edges of the gutter are bent over the bars of the modified Thomas's splint which is now almost universally used for such cases. Holes are cut in the zinc, if necessary, to allow the passage of the drainage tubing. When the zinc covers the wound, not more than a couple of layers of gauze should be placed between the two. The external dressings are applied over the zinc; any sharp edges which might cut into the skin are rounded off and padded. The apparatus may require removal and thorough cleaning about once a week.

DRAINAGE AND THE KIND OF DRAIN.

The primary object of drainage is, of course, to prevent accumulation in dead spaces of fluids which will form favourable media for the growth of pathogenic micro-organisms, and which, on physical grounds alone, will prevent or delay healing by keeping the tissues from adhering. All the same, if the dead space is not large and can be obliterated by suitable bandaging, if the effusion is likely to be small in amount, and if the wounded part has been rendered aseptic—as, for example, after excision—then there is really no necessity for drainage. In certain cases—for example, when slight infection of the knee-joint or of the brain exists—the presence of a foreign body such as a rubber drain, and still more a glass or metal one, in the affected part will probably allow the sepsis to gain a firm hold, especially in the parts bruised by the drain—the very thing the drain is meant to prevent.

"Down to but not into."

The more delicate or highly organized a tissue is the more damage is likely to be caused by the introduction of a drain, especially a rigid one. Experience has shown that the principle of introducing such drains "down to but not into" the important structure or cavity which has to be drained is sound. It matters not whether brain, shattered bone, pleural or synovial cavity has to be drained—this principle holds

good. This refers to the preventive function of the drain that is in use when the infection has not yet obtained a firm hold.

When infection is really well established, and is already causing suppurative encephalitis, osteomyelitis, or synovitis, the matter is more difficult and requires much judgement. The presence of decomposing blood-clot, loose purulent lymph-clot, or even of offensive pus in a joint, although the synovial membrane be swollen and injected, does not mean that the joint is inevitably doomed to destruction. Many brilliant results have been obtained, even in the knee-joint, which was thought to be particularly vulnerable, when the cavity has been cleansed thoroughly of foreign bodies and purulent contents, washed out with saline solution of appropriate strength, and then drained by a tube which led down to but not actually into the hole in the synovial cavity. In some cases—and this depends on the character of the wound left after operation—leaving the wound open, no drainage being inserted, and protecting it from secondary infection seems to be an equally efficient method. Absolute fixation of the joint afterwards is indispensable to success.

Drainage of the brain, when abscess has formed round imbedded bone or foreign body, is a very difficult matter; rigid drains are particularly harmful to the brain. This is especially true if holes be cut, for the intracranial pressure forces even normal brain through the holes or the end of the tube; moreover, the constant friction of the pulsating brain against the hard foreign body must have a bad effect. The most satisfactory drain seems, on the whole, to be a piece of jaconet, batiste, or similar substance, folded concertina-wise, with small pieces of salt tablet imbedded in its folds. As the salt dissolves it exerts a hypertonic effect on the surrounding inflamed brain. If, however, the pus be particularly thick or profuse, it may be necessary to insert, in addition, a tube for a short distance and for a short time.

A drainage tube thrust amongst the fragments of a shattered bone will tend to carry infection, and in any case to cause necrosis of the fragments in contact with it. A drain on each side, down to but not into the shattered mass, will do all that is required.

Rigid drains in contact with pulsating vessels predispose to secondary haemorrhage. In a septic wound they are practically as efficient in causing this as are displaced fragments of bone or pieces of missile. When drainage of wounds which expose large vessels is required, the advantage of transverse incision of muscle or cone-shaped excision is obvious, together with, possibly, the use of the absorbent bandage drain.²

It is not, as a rule, good practice to draw a non-collapsible drain through the whole length of a wound, unless the track is superficial. Even if it is, it is in most cases quicker and safer either to excise and suture the wound entirely or to lay it open and make secondary suture as soon as it is healthy. It is especially dangerous to draw tubes through between the bones of the forearm or leg. The tube is likely to cause, from its pressure, sloughing of the interosseous membrane, secondary haemorrhage from the vessels which lie close to the membrane, and paralysis from destruction of the nerves which accompany these vessels.

Removal of Drains.

When the wounds are healthy, and if there be no necrotic tissue in the depth, it is desirable to remove drains altogether, provided the surfaces of the wound are forced in contact, but it is probably safer practice to shorten them gradually. Rigid drains should give place to soft drains (jaconet, batiste, torn glove, or absorbent bandage) as soon as the discharge ceases comparatively to be profuse. This is usually when necrotic tissue has been cast off or absorbed.

Tension.

Tension in a wounded part militates against successful treatment. It interferes with the efficient circulation essential for the combating of infection; parts which are best supplied with blood—for example, the scalp or face—heal most quickly. Therefore, another great principle is established—that the tension must be relieved, whether in a joint, in the thigh, in the chest, or in the brain. The extensive incisions which are advocated in many cases probably do as much good by relieving tension as by providing free drainage.

REMOVAL OF FOREIGN BODIES.

Whether foreign bodies should be removed depends, firstly, on their size, shape, character, and position, which determine the amount of infective material carried in to the wound; and secondly, on the mobility of the part in which they are lodged and the probable effect on its function. The more important the function the greater is the necessity for early removal.

The amount of infection carried into a wound depends chiefly on the shape and roughness of the missile, and whether it has traversed the patient's clothing. An undistorted rifle bullet carries in a negligible quantity. Shrapnel balls, distorted rifle bullets, and fragments of shell practically always carry in sufficient to cause inflammation. But shrapnel balls and fairly smooth pieces of shell may be quickly wiped so clean during transit through the tissues that they do not cause infection where they lodge. It may quite often be observed that while sepsis becomes established around the entrance wound, the deeper parts of the track remain or become sterile, and no inflammation occurs around the missile itself, so that it can often be removed aseptically through a fresh incision.

All are agreed that irregular fragments of shell, distorted rifle bullets, and superficial shrapnel bullets should be removed as soon as possible. Difference of opinion exists concerning the necessity for and proper time of removal of undistorted rifle or shrapnel bullets or small pieces of shell which are not causing trouble or which are difficult to reach. The decision should really be governed by the importance of the structures in or near which they are imbedded, and the amount of movement which ordinarily takes place. Thus, if buried in bone—in the condyles of the femur, for instance—a rifle bullet almost always, and a shrapnel bullet very frequently, heals in, and may remain permanently without causing irritation. If in the belly of an important muscle any foreign body, unless comparatively minute, will sooner or later have to be removed. It is dangerous to leave any kind of foreign body in close proximity to a large pulsating vessel. Ultimately it will cause secondary haemorrhage or aneurysm. The more irregular it is in shape the sooner will trouble occur.

The structures forming a joint lie, ordinarily, in such close proximity during movement that there is no room for any extraneous material. While an aseptic foreign body, lying free in a joint, may cause no irritation so long as the joint is kept at rest, very rarely can the joint be moved to any extent without lighting up trouble, so that removal as early as possible is indicated. Much more is this the case when sepsis is present.

It is remarkable and somewhat inexplicable that in some quarters it is apparently the practice to treat the brain—possibly of all organs the most important, the most delicate and the most susceptible to continued irritation—on a different principle. I need only say at present that it seems very unjust to the patient that his brain should be selected as an exception to a principle whose application is attended with such success in other parts of the body.

X RAYS.

The importance of accurate localization has been borne in on us all in various ways from time to time. When a special localizer or stereoscopic apparatus is not available the part should always be skiagraphed in two planes, preferably at right angles to each other.

ANTITETANIC SERUM.

No matter how insignificant the wound, every patient should receive a prophylactic dose of antitetanic serum if there be a chance of soil having been implanted. If doubt exists as to whether a dose has been given at the front, the surgeon at the base had better make certain by giving one. The fear of anaphylaxis is an insufficient excuse for not giving the serum, but in the case of a man wounded for the second or third time it is probably safer to give it in "fractional" doses, especially if he reports having shown any of the manifestations of serum sickness after previous injections.

AFTER-DRESSING.

The tendency is to dress wounds presenting raw areas far too frequently. Experience has shown that frequent

dressing may, be very detrimental. Speaking generally, a dressing is used: (a) To protect the wound from deleterious influences; (b) to keep it at rest so that healing may proceed rapidly; (c) to soak up and thereby remove discharges which may accumulate on the raw surfaces; and (d) to act as a vehicle for substances which, by their direct or indirect action, are antagonistic to infecting organisms. A further—very important—attribute of the perfect dressing for the severely wounded man, whose nervous system is so often in a very precarious condition, is that it should be painless, at least very soon after it has been applied.

The following statements apply chiefly to large, deep, irregular wounds, which are the most complicated, but with slight modification are applicable to other types.

The superficial dressings only should require frequent changing, and they ought to be changed whenever they become soaked with discharge. They, as well as the skin, should be treated with some antiseptic application. For deep dressings, absorbent gauze is in general use. This usually adheres rapidly, and later becomes incorporated more or less with the layer of granulation tissue which appears very early. It performs an important function in preventing excessive absorption of poisonous material from the wound. It covers and nourishes the numerous small pieces of aponeurotic tissue which are exposed after such a wound is cleaned up. The gauze must be packed into a wound fairly firmly, so that the granulations will not penetrate far into its meshes. It must not be packed too firmly into the recesses, otherwise the tissues lining the wound are rendered anæmic, and the healing process is interfered with, indeed localized necrosis may occur. Good circulation predisposes to rapid healing. It is also obvious that the gauze must not be laid in too loosely, at all events during the early stages when the infecting agents may be in the ascendancy, otherwise it will act as a deleterious foreign body. The exudation absorbed by loose gauze provides abundance of foodstuffs for these microbes, and such a gauze dressing forms very soon a veritable "pus poultice" which ought to be removed as soon as possible.

The Tablet and Gauze Pack.

The gauze pack should contain in its folds some material antagonistic to the development of these microbes, and the supply thereof should be as constant as possible. This can be achieved by putting into the wound a system of tubes which carry fluid to all parts, but experience has shown that the salt "tablet and gauze pack" procures the desired result at least equally well, and with much less trouble to all concerned. When properly used it entails the least possible disturbance and pain to the patient during the early days of convalescence. A little practice teaches the operator the degree of pressure proper to be used for wounds in the different regions of the body. Such a dressing, if adherent, should not be removed unless for some very definite reason. When it is pulled off bleeding occurs, the protective barrier is broken down, the process

CHART A.—Case of amputation (O) through upper part of thigh. Several other septic wounds present. The high swing of the temperature (D, D—) ceased when the daily dressings were stopped. Observe the slight rise after the "permanent" dressing was changed (D¹).

of healing is interfered with, extensive sloughing of aponeuroses takes place, and the patient suffers excruciating pain unless an anaesthetic is given. Often the high temperature taken as an indication for changing dressings is not reduced; in fact, it may go higher still,

and it is easy to see why this should be. The patient's general condition deteriorates for a similar reason, poisons being absorbed from the wound more easily through the reopened portals. His general resisting and recuperative powers are weakened, especially on account of the strain on his nervous system entailed by the repeated painful dressings. It may be also that the tearing down of this protective barrier predisposes to the occurrence of septicaemia.

On the other hand, if the wound is properly cleaned up, if a "perfect" dressing has been applied, and if the wounded part has been efficiently fixed and supported, it will be found that in a few days the temperature is normal, the wound and surrounding parts are healthy, the patient is happy and his general condition immensely improved. If the dressing is torn off before the temperature is normal, or even within a couple of days of its having become so, the fever will probably return within a few hours. The temperature will probably descend gradually if the dressings are again left undisturbed, and will as probably continue to be remittent so long as the dressings are changed frequently. Similar phenomena are observed after secondary suture or when, after complete arthrotomy of the knee, the granulation covered articular surfaces are fixed in their normal positions (Chart B). A continued high temperature should, however, always make us search for some other adequate explanation which may not be directly connected with the wound. Metastatic abscesses are often very insidious in their development.

CHART B.—Case of severe shell wound of the knee. Arthrotomy by transverse incision. Other lateral incisions radiating from this laid abscess cavities open. Fixation in acute flexion till wounds were covered by healthy granulations. This chart indicates the general disturbance which occurred when the knee was straightened on September 20th (O). The last dressing (D) was made on September 24th.

The indications for changing such a dressing are: (a) When it is evident from the condition of the parts surrounding the wound that there is retention of pus in a pocket or that extension of the inflammation is taking place; (b) if deterioration of the patient's general condition is occurring when there is no complication present to explain it; and (c) when the deep dressing becomes so offensive that it is annoying to the patient. In the last case, however, the dressing is usually loose and ought to be removed, as it then forms an irritating foreign body.

Ordinarily, however, this "tablet and gauze pack" can be left in for many days—in test cases it has been left even for fourteen days. After the first twenty-four hours or so it often keeps wonderfully dry. Apparently this happens when the necessity for lymph lavage has passed, but no satisfactory explanation of this phenomenon has yet been afforded. There is no advantage in leaving the pack *in situ* after the temperature has been normal for three days or so. Usually in six to eight days the pack is removed, preferably under an anaesthetic. The second packing should be slightly less in extent than the first, and the bandage should be applied again fairly firmly so as to obliterate any potential dead spaces in the depth of the wound. Each successive packing should be diminished in this way. The wound, by the time it is covered by healthy granulations and ready for secondary suture, will probably be greatly reduced in size. In a case of this kind, where a huge wound situated in the upper arm was associated with severe fracture of the humerus, the dressings were changed only five times during a month; at the end of that time the wound could

be practically obliterated by properly applied strapping (Chart C).

CHART C.—Case of severe lacerated wound of arm with comminuted fracture of humerus—lodgement of fragment of shell and clothing. O. Operation for removal of dead bone. Dressed for first time on fifth day (D) after operation and packed with "tablets and gauze."

A dressing of this kind is not suitable to every case of deep lacerated wound. The extent to which the infection has progressed amongst the fragments of a splintered bone may make the use of any sort of pack dangerous. Such considerations force us to rely on other forms of treatment by simple drainage, by continuous irrigation, by baths, and so forth. It may, however, be said that practically if this form of dressing be not successful in combating the inflammation in a deep wound of the extremities the chances of saving the limb are not great, but if such wounds come under treatment fairly early its use may be recommended with every confidence. Further, seeing that this dressing acts so satisfactorily in some types of complicated wounds, it should not be impossible to find one which will be equally satisfactory in other types.

EXCISION OF WOUNDS.

As I have pointed out,³ many "gutter" or even "punched-out" wounds, some of them of large extent, can be excised and sutured at once, with great advantage to the patient and to the military service. It is unnecessary to discuss this procedure again. The results obtained afford ample justification for a wider employment of the method.

SECONDARY CLOSURE OF WOUNDS.

When the surface of the wound is covered with healthy granulations, and bacteriological examination shows that no specially dangerous organisms are present, many wounds can be closed with safety, provided no dead spaces in the depth are left undrained. When the granulations are flabby and the discharge profuse, it is necessary to prepare the surface for a few days beforehand. When a wound is thus unhealthy, a change to some kind of dressing other than that previously employed is indicated. Changing the strength of the salt solution, "spirit" dressing, the employment of astringent antiseptics such as acetate of alum, red lotion, picric acid, or in some cases glycerine, will be found efficacious in improving the condition of the wound.

Much can be done to reduce the size of the wound before suturing by drawing the edges together with strapping or by compressing the part by suitable bandaging. The strapping should extend far beyond the area of the wound, and great care must be taken that retention of discharge in the depth does not occur. The sutures should be inserted in the same way as "relaxation sutures," or those used frequently in the repair of a ruptured perineum—that is, they should, if possible, under-run the whole surface of the wound. Suturing in layers is practically never possible. When the sutures cannot be made to catch up the deepest part of the wound, a tube of suitable size or folded jaconet or "batiste" must be inserted to drain that part. The sutures should be prevented from cutting the skin by threading them through lengths of rubber tubing ($\frac{1}{8}$ in. or $\frac{1}{4}$ in.) which, when the sutures are tied, reach from one stitch hole to the other. The sutures should be removed early and the wound held together by narrow strips of adhesive plaster or mastic varnish dressing, applied before the stitches are removed.

GENERAL CONDITION OF THE PATIENT.

I do not propose to make any remarks about vaccine treatment, but it remains for me to say that the general condition of the seriously wounded man is deserving of more attention. It must be remembered that he has probably been subjected to severe physical and mental strain for days, if not for weeks, in the fighting line. Patients who are brought in looking cheery and fit may in a few days be physical wrecks, and extraordinarily nervous and apprehensive. Owing to loss of nerve tone and the effects of sepsis everything seems to go wrong. Sleep fails. Appetite fails. Metabolism fails. Fats and proteins already in the system are used up, but oxidation is apt to be incomplete, and the patient has no desire for foods which contain them in large quantity. The great strain on the organs connected with metabolism and elimination, owing to the imperfect oxidation and sepsis, is apt to lead to their break down. The use of sedatives and general anaesthetics does not improve matters, but we cannot escape from using them, since the depressing effect of pain is to be feared even more. Sedatives have to be used freely, but those which are least harmful should be chosen. Omnopon is to be recommended instead of morphine for this reason. Similarly, ether should be used whenever possible instead of chloroform. In a large number of cases local anaesthetics, whether by spinal injection or peripheral blocking of nerves, can be used with the greatest advantage. The addition of potassium sulphate 0.25 to 0.5 per cent. to the solution enhances and prolongs the effect of local anaesthesia. Definite symptoms of "acidosis" have not often been observed, but in many of these cases the chief predisposing causes thereof are present, and we should take measures to counteract them. Thus, during the critical period, we should give alkalis in ample doses, and foods (especially carbohydrates and sugars) which are very easily assimilated, and which do not produce many complex by-products during their metabolism. The administration of these substances, and also of fluids, by the rectum should not be forgotten.

RESULTS OF A SPECIAL INQUIRY.

In the experience of the surgical workers in the Rouen hospitals, the saline treatment of septic wounds has stood the test of time, while other methods have, after trial, been found wanting. At present it is used almost exclusively, all other treatments being looked upon as auxiliary. For example, as noted above, use is made of hypochlorite solution in some special cases.

Seeing that the claims of saline treatment had been urged chiefly by laboratory workers, it was thought advisable to collect evidence from clinical workers who had obtained sufficient experience. Accordingly, in July, 1915, a list of questions was sent to twenty-two hospitals in the area, and replies were received from all. These questions and an epitome of the replies are now submitted. It can be said with justice that the experience of the last five months has strengthened the faith in saline treatment.

For hypertonic treatment, solutions of 5 per cent. sodium chloride and 0.5 per cent. sodium citrate have ordinarily been used to begin with. As has been pointed out, the varying physical conditions and infecting agents of the wounds require variations in the strength and nature of the application if the best results are to be obtained. Sodium citrate is not absolutely necessary. Plain table salt has been found perfectly satisfactory for bath treatment when large quantities have to be used. Plain glycerine, glycerine with salt or glucose, or the now old-fashioned ichthyol and glycerine, have been used in certain stages in certain infections when it is found that the simple salt solutions are not quite satisfactory. Hypertonic solutions of glucose or other sugars have not obtained favour to any extent.

Treatment by isotonic solutions can be carried out continuously only by baths, continuous irrigation, or by very frequent changing of fomentations.

Methods of Application.

Baths.—Great ingenuity has been displayed in supplementing the ordinary body, foot, hand, or forearm baths supplied. Some of the contrivances deserving special mention are: (1) Captain Donaldson's bath⁴ for wounds below the middle of the thigh, but especially for the leg or

foot. The rubber collar causes a certain amount of passive congestion, which can be increased if thought desirable. (2) Captain R. S. S. Statham's adaptation of a curved earthenware road drain, closed by mackintosh sheeting at one end, for wounds below the shoulder. (3) The arrangement of mackintosh sheeting slung to a bed cradle, depicted by Major Adye-Curran, which can be adapted to practically any part of the body.

Continuous irrigation is carried out either by the "drop method" on to gauze which is laid loosely on or into the wound, or by small tubes leading to the recesses of the wound. The overflow is conducted into a receptacle at the side of the bed by suitably arranged mackintoshes. The absorbent bandage drains recommended by Colonel Sir A. Wright are, on the whole, preferable to ordinary gauze for this method.⁶

In using either of these methods it may be advisable to smear the skin which is immersed with vaseline or some other ointment. The use of "irrigation flanges" for preventing soaking of the clothing or bedclothes will prove of use in many cases.⁷

Simple soaks or fomentations—that is, gauze or lint wrung out of varying strengths of solution—are used in the same way as an ordinary fomentation, or are simply moistened at intervals without being removed. Their action is enhanced when they are applied warm.

Tablet and Gauze Packs.—After the wound has been cleaned by operation, all the recesses of the wound—these recesses should be sought out by the finger—are filled, fairly firmly, with gauze wrung out of 5 to 10 per cent. salt solution, in the folds of which are placed numerous tablets of salt. Blood clot which may form during the packing should be wiped away. The gauze should be packed in concertina-wise, a tablet being placed between every third or fourth fold. A fairly large, fenestrated rubber tube is placed so as to reach to the deepest part of the main cavity, which is then filled with gauze and tablets. The dressing is made flush with the skin and the tube projects slightly from its midst. The surrounding skin is painted with solution of iodine or other antiseptic application. Two or three layers of gauze are then used to cover the wound and surrounding skin. A suitable amount of absorbent cotton-wool is applied and a bandage wound on smoothly and firmly.

Should pus collect in any isolated part of the wound, it is not necessary always to remove the whole of the pack, and thus to cause the patient unnecessary pain, and to jeopardize the healing of the rest of the wound. Irrigation and drainage of the affected part may be instituted. The rest of the "pack" will probably become loose in a few days. If it is suspected that any part of the wound will give trouble in this way, a drain down to that part should always be inserted.

Questions regarding Saline Treatment, sent to Twenty-two Hospitals, in July, 1915.

1. Do you find "hypertonic" treatment of wounds (by salt, glycerine, or other solution) satisfactory when compared with other methods?
2. What method of applying it (bath, continuous irrigation, simple soaks, gauze and tablet packs, etc.) do you find most satisfactory? Can you differentiate types of cases in which one method is likely to be superior to another? Do you alter the strength of the solution for different cases?
3. Is the addition of "antiseptics" to the applications of any advantage?
4. What are the indications for discontinuing the treatment?
5. Do you find that patients complain of severe pain? If so, is this pain usually long-continued? Has it any relationship to the age or condition of the wound? Do you employ any remedy to allay the pain if complained of?
6. For how long periods at a time do you apply continuous bath or irrigation?
7. Are there any special points regarding this treatment not touched upon in these questions which you wish to be brought to notice?
8. Do you still use hydrogen peroxide to the same extent? For what purpose or class of case do you find it useful?

Summary of Replies.

The following statement represents, I think fairly, the general opinion expressed in the replies to these questions:

1. The average opinion was voiced in the reply, "Yes. In the opinion of all the surgical workers of this hospital, distinctly superior to other methods." Several replies were most enthusiastic. One surgeon, however, stated

that in his experience the value of the treatment was still *sub judice*, and he was "not convinced that it fulfils the claims made for it."

2. The answers bring out clearly that the method of application must vary with the type and situation of the wound, with the condition of the wound, and the length of time since it was inflicted.

(a) *Baths* were probably most popular at that time. Practically always used in wounds of distal parts of the extremities, especially when these were multiple; where purulent discharge was very profuse, and "when heat was found to relieve pain." Warm 5 per cent. solution of ordinary table salt was most frequently used. Tablets are too expensive for making up large quantities of solution. If solutions stronger than 5 per cent. are used at first, pain is often caused. By adding a handful of salt every fifteen to thirty minutes to a big bath, the strength can gradually be increased, if thought necessary. No more salt is added after the patient begins to complain of pain. Sometimes the 5 per cent. solution must be reduced in strength by adding more water.

(b) *Continuous irrigation* was mostly used after flapless amputations: for joints which had been laid freely open and in some deep open wounds which could not be placed in a bath because movement was painful and undesirable (for example, in some compound fractures).

(c) *Simple soaks* for lacerated, shallow wounds, especially when they have begun to clean. Hot fomentations of 5 to 10 per cent. saline were strongly recommended by some for the relief of pain and to hasten the separation of sloughs.

(d) *Tablet and gauze packs* were judged to be best for deep and fairly recent wounds.

(e) *Drainage tubes containing salt tablets or suppositories* were recommended for long tracks and recesses. Colonel C. B. Lawson initiated this method. The discharge dissolves the tablets slowly, and a hypertonic action is exerted on the neighbouring tissues by the salt solution which diffuses from the tube. The good effects noted in some cases treated by this method stimulated the invention of the "tablet and gauze pack," which is now, as already indicated, most frequently used.

It is interesting to observe that in July, while some preferred to use continuous baths for cleaning deep wounds in the early stages, and then to change to packing with simple soaks or tablets and gauze, the majority preferred to use tablet and gauze packs at the beginning and after the first dressing to use baths or continuous irrigation. As faith in saline treatment became more firmly established it was almost natural that the method should be evolved of changing the packs at long intervals and reducing the size of the pack at each dressing until the wound could be closed or the pack dispensed with. This development has been attended by great success. Pain, time, trouble, material, and expense are saved.

3. The general opinion was that the hypertonic treatment had been so satisfactory that it was unnecessary to add antiseptics. One surgeon thought that antiseptics retarded the action of the salt. One added "a little carbolic or lysol if the wounds have a markedly offensive odour." Of course, all used antiseptics for cleansing the skin around the wound. (The attitude at present towards "eusol" or hypochlorite solution is neutral, in some cases "benevolently neutral"!)

4. The general opinion was that the treatment by salines may be discontinued when the wound is clean and covered by healthy granulations. Some added, "when the temperature is normal," "when there is a tendency for the wound to bleed," and "when granulations become exuberant and flabby." One surgeon replied, "On cessation of the acute discharge and anaemia." It was pointed out that in some cases the profuse lymph flow, provoked especially by baths and continuous irrigation, "drained" the patient's strength and tended to make him anaemic. The continuous gauze pack does not have this effect.

5. Extraordinary variety of opinion was expressed in the replies. Some stated that little or no pain or only transitory pain was complained of. Others said that pain was often severe, and lasted for fifteen to thirty minutes. A general opinion seemed to be that it depended more on the type of patient than on the type of wound. Direct application of tablets to raw surfaces seemed to be productive of most pain; occasionally it caused sloughing, especially of granulations. It was suggested that manipulation might be the cause of pain after packing had been used. It was rare to have patients complain of pain if general anaesthesia had been employed for the packing. (An anaesthetic should always be used to ensure proper packing of a large wound.)

Regarding the relation of the age or condition of the wound to the amount of pain produced, some regarded the

early "tissue shock" as rendering the patient less liable to pain; others said that if the wound was recent and "clean," the pain was greater than if the wound was a couple of days old and in a sloughy condition. The general opinion seemed to be that when sloughs began to separate and granulations to appear salt or glycerine dressings were apt to be painful, and that this was an indication to reduce the strength of solutions, or to change to some other kind of dressing.

The use of salt dressings had not provoked a larger use of such remedies as aspirin or morphine to relieve pain. It was pointed out that it is especially important to cut nerves short in amputation stumps when hypertonic saline dressings are to be applied to the raw surface. The suggestion was made that sulphates (magnesium or sodium) instead of ordinary salt might be used. (They have apparently a good effect in reducing pain, but have not been tried extensively. The necessity for their use is not great, and less is now heard about pain.)

6. Some used baths only for two hours at a time—two to four or more applications in twenty-four hours. Some gave only one bath a day; others used baths continuously for as long as forty-eight to seventy-two hours, or even longer, with good results, and without complaint from the patient, except on account of the irksomeness. One disadvantage of these methods is that they are "more troublesome to the patient and to everybody else." The general rule seemed to be to use baths and irrigation during the day and soaks or irrigation by night. They were discontinued when the sloughs had separated.

7. Any recommendations elicited in replies to this question have already been incorporated in the paper. Colonel C. B. Lawson pointed out that "warming the dressing, as with a hot-water bottle, greatly increases the lymph flow." Several surgeons drew attention to the fact that the salt tablets are "opaque to α rays, the density being midway between that of bone and metal."

8. The majority of replies stated that hydrogen peroxide was used very occasionally. Practically all used it only for its mechanical effects, especially in loosening dressings. (It is used less than ever now.)

December, 1915.

SENSITIZED SHIGA AND FLEXNER VACCINES IN THE TREATMENT OF CHRONIC BACILLARY DYSENTERY.

BY

SIR LEONARD ROGERS, C.I.E., M.D., F.R.C.P., I.M.S.,
PROFESSOR OF PATHOLOGY, CALCUTTA.

At the present time chronic bacillary dysentery is the most difficult and unsatisfactory of the more common bowel diseases in warm climates to treat, causing much misery and invaliding, while in the native population, among whom neglected cases are commonly met with in civil hospitals, the mortality is very high.

The introduction of dysentery vaccines some years ago, especially by Forster of Lahore, was an important advance, and a number of good results have been recorded from its use, chiefly in Indian gaols, although it failed in some of them. Unfortunately its use is not without serious drawbacks. In one case in Calcutta fatal gangrene of the bowel closely followed the repetition of the same dose which had previously been given without ill effect, while I have several times seen serious recrudescences of the disease produced by vaccines prepared in Forster's own laboratory, leaving the patients worse than before its use. Moreover, R. T. Rodgers¹ reports from the Raipur Gaol, Central Provinces, two cases treated with Forster's vaccine in which a severe negative phase, characterized by an increase in the symptoms lasting three to six days, followed its use, and ended fatally on the fourth and fifth days respectively. In one of these perforation of the large bowel with acute inflammation and congestion throughout was found *post mortem*. These unfortunate results are clearly due to the great amount of intracellular toxins in dead Shiga bacilli, for it is well known that an injection of the dead organisms into rabbits produces

necrosis of the mucous membrane of the large intestine, with all the pathological changes associated with acute bacillary dysentery, showing that these toxins have a selective action on the large bowel mucosa.

The foregoing considerations led me a year ago to apply Bedeska's principles to the preparation of a sensitized dysentery vaccine, in the hope of being able to prevent severe and dangerous reactions, and at the same time retain the beneficial action of the remedy. During the past year my opportunities for testing the sensitized vaccines I have prepared have been almost entirely limited to patients seen in consulting practice, still the severe reactions have been so entirely absent and the results sufficiently favourable to make it advisable to place them on record, especially now that many cases of dysentery are being reported from the Eastern theatres of war, which are likely to be partly at least bacillary in nature. I had hoped by this time to have been able to report the results of a carefully controlled test of my sensitized dysentery vaccines in the Assam gaols, which is being carried out, thanks to the kindness of Colonel H. E. Banatvala, I.M.S., but during the recent rainy season the dysentery cases were unusually few, so sufficient data are not yet available. In a few Indian patients treated by me in the isolation ward of the Medical College Hospital the results have also been favourable, but they remained such a short time under observation that it would not be safe to draw any conclusions from them.

The Lister Institute antidysenteric serum was used for sensitized stock cultures of Shiga and Flexner bacilli in the preparation of the vaccines.

The following are brief notes of a consecutive series of cases treated with my sensitized vaccines during the past year. In order to avoid the danger of conveying an unduly favourable impression I will begin with the failures.

I. Cases in which the Treatment Failed.

1. An Indian gentleman came down from Bihar to consult me for chronic amoebic dysentery, which yielded to emetine injections. He returned six months later, when the stools presented the characters of bacillary dysentery, although at first I failed to isolate the organisms. He improved for a time under injections of sensitized Shiga vaccine, but still occasionally passed thick mucus without blood, and I now isolated dysentery bacilli from his stools and wished to try an autogenous vaccine, but by the time it was ready he had passed into other hands, having been told he was suffering from "mucous colitis."

2. An Indian lady brought from the extreme South of India by her husband, who is a medical man. She had suffered from griping pains with the passage of mucus for several years, and had tried all kinds of treatment in various places. I found Flexner bacilli in her stools, and treated her for nearly two months with both sensitized Shiga and Flexner vaccines, with only temporary good effect. She is now having an autogenous Flexner vaccine, but has left Calcutta and I have not heard the result.

In these two cases only temporary benefit was obtained. The maximum doses given did not exceed 100 million, so possibly greater benefit might have resulted if more prolonged treatment with larger doses had been possible.

II. Cases Much Benefited, but which Relapsed Later.

3. A young adult European in Government service came to consult me from the Central Provinces for very chronic dysentery of long standing, accompanied by severe griping pain which greatly interfered with his work, and had led him to decide to retire from India if not better soon. I cultivated Flexner bacilli from his stools, and treated him with sensitized Shiga and Flexner vaccines, as I have more than once seen greater benefit follow a Shiga vaccine in cases showing Flexner bacilli in the stools than from a Flexner one—an observation which is easily understood in view of Dopter's work, showing that the bacteriolytic sensitizing substances produced by every one of the different varieties of dysentery bacilli are identical. The injections were continued after he left Calcutta by Major Fleming, I.M.S. After two doses of 50 million and one of 100 million at weekly intervals, he wrote that it had certainly done him a lot of good, as he had had no relapse, but still had a little pain in the left hypochondriac region at times, but his bowels were quite regular. Two months later Major Fleming kindly reported that the patient was

"enormously better, and in fact at times seems to be all right." Soon after Major Fleming was transferred, but on inquiry he recently informed me that he had heard that the patient had another attack of colic and had gone to England. In this case the benefit lasted several months, while particulars of his apparent relapse are not available. Here, again, larger doses and longer treatment would probably have produced more lasting benefit.

4. A European lady was sent down from up-country to consult me for chronic dysentery of four months' duration, with the passage of large quantities of mucus, described by her doctor as "regular sheets of mucous-like sloughs." Finding the disease to be bacillary in nature, I supplied some doses of 50 and 100 million sensitized Shiga vaccine, but the immediate effect of the first doses was reported as being slight. Four months later the patient wrote from England that the injections of vaccine had done her a lot of good, but she was then suffering from a relapse of a much milder form. Her statement was confirmed by her medical man, who asked for some more of the vaccine. This was sent, but there has not been time to hear again regarding her progress.

III. Cases Greatly Benefited by the Vaccines.

5. An Indian gentleman from the United Provinces consulted me for dysentery of eighteen months' standing, complicated by fistula, which had been freely opened up into the rectum. Large quantities of mucus were being passed, from which I isolated Flexner's bacillus and made an autogenous vaccine. After one dose of 50 million, which had little effect, a second dose was not taken until after two months, when much benefit resulted. Three more doses of sensitized Flexner vaccine of 50 and 100 million were injected, and two months later the patient reported that except for a little mucus on one day only he had kept quite free from his old trouble, very marked benefit having resulted from the vaccines.

6. A European male, sent to me from the Central Provinces by Lieutenant-Colonel Chapman, I.M.S., with a history of chronic dysentery for eight months. Among other forms of treatment, he had received two courses of emetine (one in Bombay), albugin enemata, which did good for a time, a course of coli vaccines, and a mixed dysentery vaccine from Kasauli, but without any lasting benefit. I cultivated dysentery bacilli from his stools and supplied him with doses of 50 and 100 million sensitized Shiga vaccine, which Major Chapman injected. Two months later the patient wrote that the results were quite satisfactory, the symptoms having been greatly reduced and his general condition improved. He went to Europe on ordinary leave soon after, with a supply of vaccine, to enable the treatment to be continued if necessary, and I have not heard of him since.

7. An Indian male, seen in consultation with Dr. S. C. Mallik. He had been suffering from chronic dysentery for about eighteen months, and was in an extremely emaciated and enfeebled condition, being unable to sit up in bed without help. All kinds of remedies had been tried without avail. I injected 50 million sensitized Shiga vaccine, and repeated the dose after a week, as the first injection had produced a marked improvement in the bowel condition. The dysentery now finally ceased, but a third dose was given later as a precautionary measure. He remained in a very weak condition for over a month with great nervous prostration, but eventually made a good recovery. I have no doubt that the vaccine treatment saved his life.

8. An Indian female, seen in consultation with Dr. Tarak Nath Sur, to whom I am indebted for reports on the progress of the case. She had been suffering from chronic dysentery for several months, was reported to be passing about forty small stools a day, with mucus and a little blood, evidently due to ulceration in the lower part of the large gut. No amoebae were present in the stools, while the microscopical characters were those of bacillary dysentery, although I did not succeed in isolating the dysentery bacillus. Emetine and numerous other forms of treatment had been tried without avail. Sensitized Shiga vaccine in doses of 50 and 100 million were injected weekly, and rapid improvement resulted. A slight relapse occurred several months later, but quickly yielded to the same line of treatment, the good effect having been very remarkable in this case.

9. A European male had been treated with emetine and salines for an attack of dysentery, but was still passing much mucus, which was increasing in amount. His stools presented the characters of chronic bacillary dysentery, and I injected him with one 50 million and four 100 million doses of sensitized Shiga vaccine at weekly intervals, with the result that the trouble completely disappeared. This was not a severe case, but the patient was greatly worried over his condition.

10. A European male, who had been attacked with dysentery eleven months previously, and had received twenty-three injections of emetine without any marked effect. After a change of climate he gradually got better, and six months after the attack commenced was practically well. A month later, with the onset of the rainy season, the trouble returned and continued for three months, emetine, Dover's powders, etc., failing to do any good; so it was decided to send him home. At this stage I was called in consultation, and examined a stool microscopically, which presented the characters of chronic bacillary dysentery, and showed no amoebae. I arranged for him to have one 50 and two 100 million doses of sensitized Shiga vaccine. He greatly improved after the first dose, and after the second he remained free from all symptoms for several weeks. He then passed a little mucus on one day only, and received an injection of 200 million of the same vaccine, after which he had no more trouble up to the time he went on his ordinary leave a few weeks later. He himself described the effects of the injections as being marvellous. It is, however, too early to say if the effect will be lasting.

11. An Indian male, who had suffered from occasional attacks of griping pain in the region of the hepatic flexure and descending colon for several years, while during the last six months the trouble had been present almost daily, the pain waking him up in the early morning hours, and mucus being passed on rising. He had been injected with emetine without benefit. There was tenderness over the descending colon, which felt thickened. The microscopical characters of the mucus were those of bacillary dysentery, and I isolated dysentery bacilli, which proved later to be Shiga's bacillus. Mixed sensitized Shiga and Flexner bacilli were injected in increasing doses up to 125 million. In the night following the first dose there was no disturbance and no mucus was passed in the morning, and two weeks later, when I last heard, he still remained free from all symptoms. All his stools were seen by his Indian medical attendant, and a number of them by me, so there is no doubt about the facts. This case is too recent to judge if the effects will be lasting, but the immediate result of the vaccine was most remarkable.

CONCLUSIONS.

In none of the above cases was anything beyond a moderate degree of reaction at the seat of the injection of the vaccine observed, while there was never any increase in the bowel symptoms or other toxic signs for a single day. The sensitization of the vaccines appears therefore to have fulfilled the expectation which led me to prepare them. Considering that the majority of the patients were sent from various parts of India to consult me after the failure of prolonged treatment of different kinds, and that the doses used were always small—probably much less than might be used with advantage in cases which resist the treatment—I think the results recorded in this paper may be considered as affording good grounds for hoping that, with further experience, this line of treatment will prove to be an important advance in dealing with intractable cases of chronic bacillary dysentery. Sensitized vaccines also appear worthy of cautious trial in quite small doses, but with shorter intervals, even in the more acute stages of the disease.

REFERENCE.

¹ *Indian Medical Gazette*, November 19th, 1913, p. 434.

THE General Council of the Seine and the prefect of police of the department have placed a bust of the late Dr. Emile Reymond in the operating theatre of the hospital at Nanterre, to which he was surgeon. It may be remembered that Dr. Reymond, who was a member of the French Senate and an enthusiastic airman, died from wounds received during a reconnaissance in the early part of the war.

A CASE OF CHOLO-HAEMOTHORAX.

BY
T. R. ELLIOTT, F.R.S., F.R.C.P.,
TEMPORARY CAPTAIN R.A.M.C.,
AND
HERBERT G. M. HENRY, M.D.,
TEMPORARY CAPTAIN R.A.M.C.

THE main interest of the case described in this note is that the patient made a relatively straightforward recovery, despite the unusual nature of his wound, and that it never became necessary to open the chest. The history of the injury was briefly this: A bullet fired by a sniper at short range went horizontally through the man's body, drilling a hole through each arm above the elbow, and passing through the chest behind the sternum at the level of the sixth costal cartilages close to the base of the heart. Its track through the left chest must have been fairly near to the surface, perhaps just grazing the heart, but in passing out through the right side the missile had gone deeper, injuring both liver and lung.

On the eleventh day the right pleural cavity was found to be full of fluid, the percussion note being dull almost to the clavicle. By an incomplete aspiration 40 oz. of dark brown fluid were withdrawn, and this appeared to be the usual fluid from a haemothorax. Dry pericarditis developed and a dry pleurisy on the left side. The physical signs soon indicated a reaccumulation of fluid on the right side, and on the sixteenth day a second aspiration obtained 60 oz. of fluid that was dark brown in tint, but yielded a yellowish-brown deposit containing bile. Ten days later 80 oz. were withdrawn, and this was now greenish-brown in colour and almost free from blood. The operation had to be repeated, and in all the patient's chest was aspirated five times on the right side, and 15 pints of fluid in the aggregate were withdrawn. This fluid was at first serum from clotted blood, but later it consisted only of pure thin bile. The last aspiration was on the forty-ninth day after the wound. In the ninth week he was well enough to walk freely about the ward, and he was then transferred to England. At the end of the fourth month he had almost completely recovered.

The pericarditis and dry pleurisy on the left side were accompanied by fever and a good deal of pain, so it may be inferred that they were due to a smouldering infection in the serous membranes close to the septic wound of entrance. When a haemothorax is infected with streptococci, it is often found that a dry pleurisy can be detected on the side opposite to the effusion. It is difficult to believe that a pleurisy developing under such conditions has any other cause than that by a direct spread of the streptococci from the infected collection of blood; yet such a dry pleurisy will ultimately vanish, and it is very rare for it to develop into an effusion and empyema. We may therefore assume that the entry wound in the left chest of this case had admitted a slight infection into the left pleural cavity. The rest of its track was clean. The repeated aspirations introduced no infection at a later date, nor did organisms escape with the bile that was so freely poured out from the wounded liver. This absence of infection by the latter route deserves notice, for it is certain that the bile must have been leaking directly from some large bile duct.

Wounds of the liver appear at autopsy as tracks through necrosed tissue, which is stained a bright chrome yellow by the effused bile; but this secretion rapidly comes to an end, for the dead cells are soon walled off by a barrier of fibrous scar tissue. A persistent leak of bile can only come from a hole in a duct, which is fed by the secretion of live cells further up the stream and away from the patch of injury. It is generally believed that microbes appear from time to time in the larger bile ducts, either in process of their excretion from the blood or by direct ascent from the duodenum. However, it is obvious that in the case here described the bile must have remained practically sterile, for bacteriological examination of the aspirated fluids never revealed the organisms whose inroad was feared. There was another reason which, as Sir George Makins pointed out to us, might have necessitated resection of a rib. The biliary fistula lay through a tear in the diaphragm, and so long as this opening led freely into the pleural cavity, and away from contact with any

granulating surface, it seemed unlikely that the fistula would soon be closed. Resection of a rib might have been expected to bring the diaphragm into contact with the pleural wall, and ensure a rapid closure. As a matter of fact this was never needed, for the fistula closed spontaneously at about the sixth or seventh week.

Before recounting the full clinical details of the case, we may quote in this connexion some other examples of liver injury associated with wounds of the chest, which were observed by one of us in a large series of the latter wounds. The liver is often perforated by gunshot wounds without any obvious result. Since there is only the track of the bullet to suggest that the liver has been injured, and since one can never be sure in any individual case what was the position of the diaphragm at the moment when the wound was received, it is of little value to tabulate the number of men in whom the liver was supposed to have been wounded without ill results. A wound of the liver is either rapidly fatal from haemorrhage, or in itself is of little importance, for, thanks to the double blood supply, the breach in its tissue is soon healed, while biliary fistulae are neither common nor permanent.

In four men who died with a haemothorax infected by gas-producing anaërobic bacilli it was found that the liver as well as the lung had been wounded, and that the lacerated track through it was infected. But the probability is that the infection in all these four cases was carried in from outside by the entering missile, and that it did not originate with intestinal bacilli liberated from the debris of the torn liver. No facts have been observed which would suggest that a wound of the liver is peculiarly liable to be septic.

Two cases of external biliary fistulae were observed in the total series—roughly, 500 in number—of all chest wounds; and there were also two internal fistulae, of which one was the case detailed in this paper, while the second was a fistula into a bronchus.

CASE I.—External Fistula. (Under Captain W. B. Oliver.)

A sterile haemothorax on the right side caused by a bullet traversing both sides of a man's chest from left to right. From the exit wound in the fifth space, below and external to the right nipple, yellow bile began to leak on the tenth day. On the thirtieth day this ceased, and the sinus closed. There was no infection of the haemothorax, nor any alteration in its size. Three months after the wound the patient was reported by Mr. A. R. Anderson of Nottingham to have made a good recovery, with a practically normal chest.

CASE II.—External Fistula. (Under Lieutenant G. R. Colquhoun.)

A septic haemothorax caused by a bullet traversing the right base of the chest. About the seventh day there was a rapid increase in the displacement of the heart, and an exploration of the chest found offensive gas and pink pus with gas-producing bacilli. A rib was resected on the ninth day. No jaundice. On the thirteenth day bile began to leak from the empyema tube, which was a very short one, since the lung had expanded well at the operation. On the twenty-eighth day the leakage of bile had ceased, and the sinus was closed by the thirtieth day. The patient was transferred to England in good condition.

CASE III.—Internal Fistula. (Under Captain St. J. D. Buxton.)

Into the bronchus, closing about the tenth week. A septic haemothorax of the left side, caused by a shrapnel ball which traversed both sides of the chest. At some time after the wound the patient began to expectorate sputum mixed with yellow bile, but the precise date of this could not be ascertained because the symptom had caused a psychical obsession which made all the patient's statements on the question unreliable.

On the twenty-sixth day the empyema on the left side was drained; it contained streptococci and gas bacilli. Frothy sputum, with patches of bright yellow bile, and once or twice with fleshy masses of necrosed liver (proved by microscopic section), continued to be coughed up. Lieutenant-Colonel H. P. Hawkins reported from England that the expectoration of bile ceased in the tenth week. The empyema sinus was practically closed at the fourteenth week, and the patient then was rapidly becoming fit again.

CASE IV.—Internal Fistula. (Under Captain Hector Smith.)

Into the pleural cavity. This closed about the seventh week. The patient, while bending over to lift up a sandbag, was shot at short range by a sniper. He felt winded, and was carried away at once on a stretcher. No haemoptysis, either then or subsequently. The bullet passed through the flesh of the left upper arm, entered the left chest over the sixth rib in the nipple line, escaped at the same level on the right side, but an inch or more external to the nipple line, and then traversed the muscles of the right upper arm. Its track ran behind the sternum, and was at a much deeper level in the right chest than in the left.

3rd day.—Says that he felt sick, and then vomited a little blood. Otherwise no evidence of injury to stomach.

12th day.—At base hospital. No pain with food, and no sickness. Slight icterus in conjunctivæ. The entrance wound on the left side was septic. Right chest dull up to first space in front, and heart's apex beat displaced two inches to left.

Aspirated in axilla. Intrapleural pressure = 0. The volume removed was 40 oz.; final pressure = -6 cm. water. Clots of fibrin blocked the cannula and prevented complete removal of the fluid, which was of a dark brown coffee tint and sterile; it contained a few endothelial cells and lymphocytes and yielded a moderate secondary clot.

17th day.—Pericardial friction all over cardiac area and dry friction also in left axilla. Temperature upheld at 101°. Pulse 110. Aspirated in fourth space just below nipple. Initial pressure = 0, volume = 60 oz. Oxygen 500 c.cm. introduced, so that final pressure fell from -18 to -5 cm. water. Dark brown fluid, with yellowish-brown deposit containing fat globules and crystals (? tyrosin). Few old red corpuscles, and fairly numerous polymorphonuclear cells. Sterile.

26th day.—No icterus. No pericardial friction. Slightly tender and rigid in right hypochondrium. Temperature oscillating about 100°. Looks thin and ill. Heart apex beat displaced to mid-axilla. Aspirated 80 oz. greenish-brown fluid. Oxygen 1,100 c.cm. introduced so as to enable complete aspiration, and final pressure = -12 cm. Bright yellow deposit of bile; fairly numerous polymorphonuclear cells.

30th day.—Attack of pain in left axilla, and fresh signs of coarse pleurisy. Temperature 103°.

32nd day.—Aspirated. Initial pressure = -8 cm. Volume = 60 oz. Oxygen 500 c.cm., and final pressure = -20 cm. Green fluid, with greenish-yellow deposit; few polymorphonuclear cells. No secondary clot, and no coagulable protein on boiling.

35th day.—Heart apex beat still 1 in. to left. Coarse pleuro-pericardial friction.

40th day.—Aspirated. Initial pressure = -7 cm. Volume = 60 oz. A little oxygen used, and final pressure = -22 cm. Green fluid, as before. Thenceforward the temperature remained normal, after forty days of irregular pyrexia.

54th day.—Up and walking about. Heart apex beat almost normal. By x ray, only a little fluid at right base. Chest moving fairly well, but somewhat collapsed.

57th day.—Putting on flesh rapidly; transferred to England.

72nd day.—Irregular fever, lasting for eight days, reported by Dr. Ormerod; cause unknown.

120th day.—Discharged to convalescent home. Heart apex beat just internal to nipple. No sign of fluid at right base, but friction heard and movement impaired. Not yet actually fit for service.

Two or three subsidiary points deserve attention in respect of these cases. In the last example quoted the patient was not jaundiced, and he exhibited only the slight icterus of the conjunctivæ that is frequently seen in the second week of an ordinary hæmothorax; yet his pleural cavity was full of thin bile. The absence of jaundice was due to the relatively slow absorption from the pleural surfaces, when coated with a layer of blood clot. Indeed, this explanation applies equally to its absence in a hæmothorax, as well as to this case of biliary fistula. Hæmorrhage into the abdominal cavity leads at the end of the first week to a jaundice of far deeper tint, for absorption from the peritoneal surfaces is much more rapid than in the chest.

The colour of the biliary fluid in the effusion into the pleural cavity was green. Yet the deposit was yellow, and this was also the colour of the bile discharged in the bronchial fistula and in the two internal fistulae—a yellow almost as bright as that which is seen around a lacerated missile track through the liver. Bilirubin seems to have been changed into biliverdin by some process akin to that by which dissolved hæmoglobin in the fluid of a hæmothorax is often converted into a darker pigment resembling methæmoglobin.

The biliary effusion remained sterile. It is uncertain to what extent the properties of the bile itself acted as a check on the development of infection by other than organisms of the *Bacillus coli* group. But it deserves note that the bile did not cause much irritation of the pleural membrane. The polymorphonuclear cells which were found in the aspirated fluid were not more numerous than those that are often seen in an ordinary sterile hæmothorax fluid, and they disappeared before the leak of bile had ceased. The biliary effusion yielded no secondary clot, either when allowed to stand after aspiration or after the addition of fibrin ferment to it; and it contained practically no coagulable protein. Therefore it had not been augmented by the addition of an inflammatory pleural exudate.

DR. W. G. GRACE, the famous cricketer, left estate of the value of £7,278, with net personalty £6,590.

AN IMPROVED METHOD OF LIFTING PATIENTS ON TO HOSPITAL SHIPS FROM BARGES AND BOATS.

BY

COLONEL A. W. MAYO-ROBSON, C.V.O.,

CONSULTING SURGEON TO THE MEDITERRANEAN EXPEDITIONARY
FORCE.

In the war that is now being carried on at the Dardanelles it is practically impossible to deal with the sick and wounded ashore. It has therefore been found necessary to institute a fleet of hospital ships to which these patients may be transported at the earliest possible moment.

From the shore the seriously wounded, lying on stretchers, are brought out on barges or boats, from which they are hoisted on to the ships, which stand high out of the water.

In calm weather large wooden trays have been used, which are raised by cranes and deposited on the ship's decks, but in rough weather these heavy trays are a source of danger both to patients and attendants, and in any case are somewhat slow in operation, so that it takes a considerable time to unload a barge full of stretcher cases.

The new sling invented by Lieutenant-Colonel P. H. Falkner, R.A.M.C., officer commanding troops, hospital ship *Salta*, is an invention that is as simple as it is efficient. It can be used in stormy as well as in calm weather, and it accomplishes the work in a quarter the time taken up by the wooden trays.

FIG. 1.—Lieutenant-Colonel Falkner's sling. Working diagram. C, "O" canvas (but any stout canvas will do). EEEE, Metal eyes to take spring hooks. HHHH, Holes in canvas sling (diameter 8 in.) for legs of service stretcher. RRR, Metal rings (diameter 5 in.). SSSS, Spring hooks. WWWW, Wire rope (1 in. in circumference).

I have seen many hundreds of patients lifted on to the different ships, so that I speak from considerable personal experience. Unknown to those who were working the slings, I timed the transfer of stretcher cases from a trawler by one crane on to the *Salta*, and I made out that 16 cases were transferred and carried off to the wards in nine and a half minutes. We were then at Cape Helles, Dardanelles, and there was a north-east gale blowing.

So far as I am able to judge, this sling solves the question of our being able to remove wounded during the stormy weather likely to prevail during the winter if the cases can be loaded on to the barges and brought off to the hospital ships. It also solves another problem—that of delay in loading—which means great discomfort and danger to patients seriously ill or wounded, since not only can the work be done quickly, but the load to be lifted is so little that hand derricks can be rigged up in parts of the ship where there is no crane, and so the patients may be brought on at more than one place if necessary.

SUGGESTIONS FOR OPERATING THE CANVAS LOADING SLING.

By Lieutenant-Colonel P. H. Falkner, R.A.M.C.

For the rapid and efficient loading of wounded from boats and barges into hospital ships and temporary hospital ships, etc., it is most important that the working party should understand its duties. Each man in the team has only one duty to perform, and care is taken that he understands this, and does nothing else during the admission of patients.

The best results are obtained by detailing a team of four men for each barge or trawler; likewise we give four slings to each winch; the ship's crew attend to the deck above, and are not interfered with by our men until the patient is taken over. The procedure is as follows:

1. Two team "stretcher men" spread out the sling over the deck of the barge.

Bearers who come from the shore, etc., with patients, carry the stretcher and place it in position so that its legs will take the holes in the canvas sling provided to receive them. The canvas I used was a quality called "O" canvas, but any stout canvas will do.

FIG. 2.—Winch hook. A, Hauling line to ship. B.B., Hauling line to barge.

The team "ringman" lifts and approximates the two metal rings, R.R., holding the wings of the sling well up, so that the two "stretcher men" may conveniently adjust the flaps by fixing the hooks S.S.S.S. into the rings E.E.E.E., and ensure the stretcher legs being in their appointed positions (H.H.H.H.).

FIG. 3.—Removing stretcher from sling.

The "ringman" now seizes the winch hook, T, and attaches his rings, R.R. He then signals to the deck that all is safe to hoist away. As the stretcher leaves the barge the "stretcher men" rapidly spread another canvas ready to receive another patient, who is already close by in the hands of the bearers. If the bearers are not yet in position the "stretcher men" may with advantage spread more than one sling over the offloading position—one over another.

The fourth man of our team receives the rolled up slings as they are rapidly passed downwards from the deck above by means of a hauling line.

D

2. When the winch swings the patient inwards over the ship's deck, two ward bearers, both facing forwards, seize the stretcher handles, taking the entire weight of stretcher as the winch rope slackens off. In this manner the wounded man entirely escapes the inevitable jar of a wooden cradle landing on the deck.

The ward bearers now remain in position, holding the stretcher at arm's length, until the rings are removed from the winch hook and the canvas sling is dropped to the deck—to enable them to advance across it.

The loading is very smooth and rapid; therefore every man of the team is, or should be if he is properly trained, working at full pressure. During rough weather the hauling lines shown in the diagram are always used. This means an extra trained man with the team below while the ship's crew control the inboard hauling line.

If for any reason there is little or no deck room on the barge, roll up the sling, with its metal rings thrown inwards towards the centre of the cloth, from one end flap to the other. By lifting one end of the stretcher the canvas may now be readily adjusted.

Or, again, it may be more convenient for the two "stretcher men" to simply lift the stretcher from the deck while the "ringman" spreads the sling.

To prevent any possibility of accident the condition of the canvas and wire should be closely inspected from time to time.

ON THE USE OF SOLUTIONS OF QUININE AS A DRESSING FOR INFECTED WOUNDS.

By SIR JOHN TWEEDY, F.R.C.S.

EMERITUS PROFESSOR OF OPHTHALMIC MEDICINE AND SURGERY,
UNIVERSITY COLLEGE, LONDON.

I HAVE read with great interest the communication of Dr. Kenneth Taylor, Pathologist to the American Ambulance, Neuilly, published in the BRITISH MEDICAL JOURNAL of December 25th last, on "The use of quinine hydrochloride solution as a dressing for infected wounds." Dr. Taylor maintains that quinine solution (1) has high bactericidal properties, ten times as effective as carbolic acid in the case of *B. abortus capsulatus*; (2) is a strong antiferment, preventing the digestion of proteins and the consequent production of a medium favourable to bacterial growth; (3) forms no stable chemical combination with proteins, so that its activity is not greatly reduced by the presence of serum or pus; (4) is non-irritating and non-toxic.

Some years ago I published a paper on the treatment of diphtheritic ophthalmia by local application of solution of quinine.¹ The reasons which led me to employ quinine in some cases which I believed to be true diphtheritic ophthalmia were as follows: Cohnheim, Recklinghausen, and Stricker had shown that the principal changes which occur in traumatic inflammation of the cornea consist of the germination of the protoplasm of the stellate corpuscles and of the immigration of leucocytes from the adjacent capillary vessels; Binz and others had proved that quinine, whether given internally or injected subcutaneously, exerts a specific influence on the processes of inflammation by hindering or retarding the germination of protoplasm or by checking the vital amoeboid movements and consequent migration of leucocytes.² Binz's experiments also confirmed the statements of many independent observers that quinine possesses in a high degree the power of arresting putrefaction and fermentation.

Cases of true diphtheritic conjunctivitis are very rare in this country, and since the time I wrote the introduction of diphtheritic antitoxin has profoundly changed the treatment of diphtheria in all its manifestations. Antitoxin is of paramount importance, but I still believe the local application of quinine to be of the greatest service; and not only in diphtheria, but in all cases of infective and sloughing ulcers of the cornea, and in many, if not all, forms of infective conjunctivitis.

Dr. Taylor's experiments and observations supply an answer to a question which has often engaged my thoughts ever since Metchnikoff promulgated the doctrine of phagocytosis. In employing, on hypothetical grounds, quinine in diphtheritic ophthalmia I was largely influenced

by Binz's observation that quinine checks the migration of leucocytes in inflammation. Hence the important question, Does it also interfere with phagocytosis? Dr. Taylor has, I think, proved that it does not.

I may add that at first I used slightly acid solutions of quinine sulphate, but for many years I have used the sulphate and hydrochloride indifferently, and have not observed any difference in their action or efficacy.

TRAUMATIC IMPLANTATION OF EPIDERMIS IN TRACK OF GUNSHOT WOUND.

BY

LIEUTENANT-COLONEL G. H. EDINGTON, D.Sc.,
M.D., F.R.F.P.S.

AN example of traumatic implantation of epidermis in the track of a gunshot wound having lately come under my notice, I venture to record it, in the hope that, attention being drawn to the occurrence, other surgeons may be induced to keep a look-out for it in cases where a healed wound opens again and to record their experience.

Private —, aged 20, sustained on July 12th, 1915, a gunshot wound through the left shoulder. He was helping to carry a wounded man out of the trench, and was stooping slightly, when a rifle bullet struck him in the back of the shoulder, and, passing forwards, emerged above the clavicle.

He rejoined his battalion for duty on August 8th. Two days later the wound "broke down," and he was attended by the regimental medical officer. On October 21st he again paraded sick, complaining of pain in the wound. Captain Pirie Watson, at this time in medical charge of the battalion, found both scars "very weak and bulging." He incised them and removed some "sebaceous material." Similar material has since been removed at intervals. On November 1st Captain Watson sent him for radical treatment to the field ambulance.

Condition on Admission.

The wound of entrance was situated over the supraspinous fossa, and about 2 in. (5 cm.) in from the point of the shoulder; the wound of exit was represented by a small scar, circular in outline, situated in the supraclavicular region, directly in front of the wound of entrance. The wound of entrance was open and granulating, and had the appearance of having recently been incised; there was scanty sero-purulent discharge. There was no visible swelling in the course of the bullet track; but on palpation hardness was distinctly felt in the anterior part of the track. There were no signs of acute inflammation.

On November 4th chloroform was administered. A probe introduced into the wound of entrance passed forwards and pointed in the scar of the exit wound. A curette passed alongside the probe removed some pale granulations, and more deeply (about halfway along the track) struck pomade-like material. The track, which was between 2 and 3 in. long, was laid open from end to end, and was found to pass under the outer fibres of the trapezius, necessitating their division. There was a very considerable amount of scar tissue, irregularly nodular and firmly adherent to the surrounding muscle fibres. During manipulation there appeared in the wound, not apparently from any particular spot, masses and flakes of dead-white material, exactly resembling desquamated epithelium mixed with sebaceous matter. The scar tissue was dissected out, a drainage-tube inserted and the wound sutured.

On cutting, after removal, into the masses of scar-tissue, one showed a small cystic cavity from which the contents had escaped. In two or three others the cut surface of scar-tissue showed pinhead areas of sebaceous-like material, which could be picked out, leaving a clean cavity.

In the absence of facilities for microscopical examination, it seemed desirable to ascertain if possible whether the wound had at first been treated with paste; but, in answer to my inquiry, the patient was positive that nothing had been injected into the wound, and that external dressings had alone been used. I was therefore confirmed in my original opinion that the case was one of implantation of epidermis with subsequent proliferation. Theoretically, there is no reason why the carrying in of one or more fragments of living epidermis should not occur in a certain percentage of gunshot wounds. It is very likely, however, that in the majority of gunshot wounds the degree of trauma is sufficient to kill the epidermal cells.

It would appear that in civil life such implantation followed by the formation of a "dermoid" is usually the result of a trifling injury, so trifling that not only may there be no history of such forthcoming, but the scar be only seen after minute examination of the skin over the

swelling. It would also be expected that the thicker the epidermis the greater would be the likelihood of its being carried into the deeper tissues. This condition obtains in the palmar surfaces of the hand and fingers, and every one knows that there is no part of the body more subject to trifling and unheeded injuries, and at the same time more likely to be the seat of "implantation dermoids." It is therefore interesting to note the occurrence of implantation in the case just recorded. The part struck was the back, a situation where the epidermis is much thinner than in the palm, and the injury, while perhaps slight as gunshot wounds go, was by no means either trifling or unheeded.

GUNSHOT WOUND OF THE SUPERIOR LONGITUDINAL SINUS.

A REPORT OF THREE CASES.

BY

A. W. NUTHALL, F.R.C.S., CAPTAIN R.A.M.C.(T.),
CASUALTY CLEARING STATION.

THE observations of Lieutenant-Colonels Gordon Holmes and Percy Sargent on injuries of the superior longitudinal sinus, recently published,¹ are so striking as to arrest the attention of all who are concerned—as neurologists, clinicians, or surgeons—with the care of cases of gunshot wounds of the skull. They have demonstrated that injuries of the superior longitudinal sinus give rise to a peculiar set of symptoms which constitute a definite clinical picture—briefly, paralysis with rigidity of the voluntary muscles, with a tendency to progressive recovery without contractures or other permanent nervous defects.

I venture to report three instances of this particular injury which have come under my notice during the past month. I was puzzling over the curious and anomalous symptoms presented by my first case when I received the *BRITISH MEDICAL JOURNAL* on October 4th (in France), and read therein their account of "the typical case," which might almost have been written of my patient. The coincidence was as remarkable as the paper was opportune and illuminating. My second and third cases died and *post-mortem* examinations were made. No. 2 was moribund on admission and died from haemorrhage; No. 3 succumbed after operation, there being extensive destruction of the brain as well as the injury to the sinus.

CASE I.

Private W. G. H. was shot in the head during the night of September 30th–October 1st. He lost consciousness at once, alarming haemorrhage occurred, and subsequently persistent vomiting. He was admitted to our casualty clearing station at 5.30 p.m. on October 1st, conscious, but in a very grave condition of collapse from loss of blood, blanched, restless, and with a rapid, feeble pulse. He said he was paralysed, and was found to be almost universally rigid. There was retention of urine, requiring the use of a catheter. There were two wounds on the top of the head, about 2½ in. apart, and on either side of the median line, the entry wound on the left side, the exit wound on the right of the mid-line and nearly an inch behind the former; they led to a perforation in the subjacent skull, situated just in front of the mid-point of the mid-line.

His mind was clear and his speech unaffected. There was no ocular paralysis; the pupils were equal and active. There was left facial paralysis of cerebral type. No other cranial nerves were affected. An examination of the fundi was not made. The arms were held tightly clasped to the body, elbows adducted to the sides and forearms flexed across the chest, hands clenched. Fingers, wrists, elbows, and shoulders were all rigid, increasingly so up the limb. He had no voluntary control over the arms. No reflexes could be elicited in the biceps or triceps. The abdominal muscles were fixed and took no part in respiratory movements; the umbilical and epigastric reflexes were absent. His legs were stretched out rigidly to their fullest extent, rotated in so that the patellae touched each other, and the feet were crossed; the feet were extended almost in a straight line with the legs, and turned inwards. He had no control over the legs. The knee-jerks were excessive; there was an extensor Babinski reflex; it was impossible to test the ankle-jerk.

Operation.

On October 2nd both wounds were excised, a flap made, and the perforating tangential fracture cleared of depressed fragments and bone debris. On picking out a sharp fragment impacted in the dura, it was found to have penetrated and to lie in the longitudinal sinus just under the edge of the bony defect. A flooding haemorrhage from an extensive ragged wound of the sinus, and of large venous trunks on both sides, was only arrested by plugging with gauze; no other method was suitable under the conditions. The flap was sutured, and drainage established through the excised posterior wound. A subcutaneous saline infusion, containing adrenalin 1 in 40,000, was given at once. Although almost *in extremis* from loss of blood, he rallied well, and was soon out of danger. The gauze was gradually removed, and finally extracted at the end of a week. The flap healed at once, but some suppuration, finding issue through the posterior wound, persisted up to the time of his transfer from my charge.

After-History.

Shortly after the operation urine was passed into the bed; in the evening the catheter was required. During the next fortnight he frequently wetted his bed; he explained that he could not wait once he felt the desire to empty the bladder. In the latter part of his stay here he had satisfactory bladder control.

On the third day after being wounded it was noted that "at times the muscles of the thighs relax, so that the knees can be flexed passively." The fingers and wrists were also much less rigid, especially the left.

On the fourth day his general condition was undoubtedly improving. There was some power of voluntary movement of the right hand and fingers (similar to athetosis), and he could move the right arm away from the body, but rigidity was present all the time and impeded these efforts; all passive movements were effected against resistance, the extensor muscles—for example, the triceps—increasing their tonic contraction against movements. Traction on any group of muscles appeared to stimulate them to a slow, vigorous contraction. The right shoulder was more rigid than the elbow, and the elbow than the wrist. The left arm was more definitely paralysed than the right in that there was no voluntary control at all over it. The rigidity was much less marked in this arm, except in the shoulder, which was as much, or even more, fixed than the right. The abdominal muscles were firmly contracted. No abdominal reflexes were present. The legs showed very little improvement. He complained of pain, "cramp," in the adductors of the thighs. The degree of rigidity of the joints diminished according to their nearness to the trunk, the ankles being quite fixed, the knees and hips progressively less so. It was now possible to flex the knees and hips forcibly and so allow him to lie comfortably on one side or the other alternately.

On October 5th, the fifth day, flaccid paralysis of the left arm was present, except in the shoulder, the pectoral muscles being very rigid. This flaccidity of the left arm became more obvious, as it persisted throughout and showed no signs of improvement, while progressive improvement occurred elsewhere. In conjunction with the left facial paralysis it remained as a partial hemiplegia.

The rigidity of the right arm cleared off rapidly, there being none present on the seventh day. Voluntary power over the right arm was only slowly regained, and only to a partial degree, the movements of the limb being markedly ataxic on the twenty-first day, coarsely inco-ordinate excursions of the arm occurring on attempts to touch any object with the index finger. He was able, however, to hold a cigarette on the seventh day, and to feed himself on the twenty-first.

The rigidity of the legs diminished much more slowly; the hips became relaxed the earliest, the knees about a week later, but some stiffness of the ankles persisted throughout. A very limited amount of voluntary control over the legs was regained. The knee-jerks were excessive, and an extensor Babinski always present. Ankle clonus was first noted on the seventh day; it became very much less marked subsequently.

Sensory changes were noticed to correspond to, and appeared to depend on the degree of, the paralysis and hypertonus of the muscles; they cleared up *pari passu* with the recovery of voluntary control and the disappearance of the rigidity. The sense of position was lost, nor was there appreciation of passive movements of the joints; thus, he could not tell whether the legs were crossed or the knees were being flexed; when his eyes were closed he could not say what was being done to the fingers, wrists, or elbows. The sensibility of the skin to light

contact was present throughout, but touch stimuli were delayed or not correctly localized. Heat and cold were not tested. The value of subjective information of this nature is to be discounted by the very desperate condition of the patient at the time; later, when he was out of danger and well on the road to recovery, the sensory changes were confined to loss of sense of position and appreciation of movement about the ankles and legs, and there was a marked improvement in this respect when he left us.

On the twenty-first day he was evacuated to the base; I have no further information about his progress. He then had left hemiplegia (face and arm), and considerable muscular wasting. There was a certain amount of control over the right arm, but its movements were feeble and very ataxic. He was still almost helpless, although there remained only slight rigidity of the legs and ankles. The wound of exit was suppurating, as if there were still a foreign body (? gauze) beneath the scalp.

CASE II.

Private F. H. was shot in the head on October 16th. He was received by us on the 17th, comatose and moribund, dying two hours after admission. He was not noticed to have any rigidity by the receiving officer.

Necropsy.

Post-mortem examination showed a wound 3 in. long transversely across the mid-line of the vertex. There was a depressed gutter (tangential) fracture, with very little loss of bone, situated exactly over the sagittal suture; a fissured fracture extended from it downwards and outwards nearly to the left external angular process of the frontal bone. A fragment of the inner table, about 1 in. square, was separated and depressed on to the sinus, and a small, sharp piece of bone had been driven into the sinus. There was a slit-like tear in the dura, about an inch in length, at right angles to the mid-line on the left side and extending across the longitudinal sinus as a laceration of its roof. The wound was situated at the junction of the middle and anterior thirds of the sagittal suture. There was no blood clot in the sinus. The margins of the precentral and superior frontal convolutions of both hemispheres were severely bruised—that is, discoloured by haemorrhagic exudation. The frontal and precentral venous trunks showed up prominently on both hemispheres as purple, thrombosed, engorged vessels, with congestion of the convolutions bounding the sulci.

In this case the brain showed a localized contusion which might easily have been recovered from. Death was probably due to haemorrhage from the longitudinal sinus, or to shock.

CASE III.

Sergeant H. E. H. was shot in the head on October 24th. He was received by us on the 25th quite unconscious. The pupils were equal and active; there was no ocular paralysis. There was general rigidity of the limbs; the arms extended by the sides of the body and rotated in; the right was less rigid than the left, allowing the passive movements without much resistance. The legs were extended and rigid, the feet turned in (but the legs were not rotated in). The knee-jerks were excessive; an extensor Babinski and marked ankle clonus were present. Urine was passed into the bed. A wound 3 in. long, through which brain matter was extruding, was present at the junction of the anterior and middle thirds of the mid-line of the head; it was transverse in direction and mainly on the left side. An operation was carried out within two hours of admission. A tangential perforating fracture, with considerable loss of bone, was exposed; there was extensive destruction of the underlying brain by deeply indriven fragments of the inner table. There was blood clot in the mesial angle of the bony defect; in clearing this out, free haemorrhage from the longitudinal sinus occurred. A crown of bone was removed from in front, and a perforation from which the blood poured, was closed by a suture. A drainage tube was placed in the cavity and the wound closed. He did not rally after the operation, but quickly became worse, and died four hours later.

Post-mortem Examination.

The lacerated wound of the dura mater was situated over the left superior frontal convolution, in which there was a large ragged cavity. The superior longitudinal sinus was torn completely across: *ante-mortem* blood clot filled the sinus for three inches behind the wound. The four main venous trunks—frontal, pre-central, post-central, and occipital—stood out prominently on both hemispheres as purple, swollen, thrombosed vessels, giving an appear-

ance of intense congestion to the greater part of the upper portion of the brain. The left prefrontal venous trunk had been destroyed.

Holmes and Sargent emphasize the favourable prognosis of injuries of the superior longitudinal sinus, but their "experience has shown that the results of surgical interference have been extremely unsatisfactory." I believe that in my two cases it would have been better to have confined the interference to strictly conservative measures. My first case very nearly died after operation; the end of the second was probably hastened by the operative interference. In dealing with a case presenting symptoms of "the longitudinal sinus syndrome" I am inclined to think that the surgeon should hold his hand until and unless the arrest of haemorrhage or the relief of definite compression is called for; in other words, there should be no interference.

A NOTE ON WICK DRAINS.

BY

G. H. COLT, F.R.C.S.,

ASSISTANT SURGEON, ABERDEEN ROYAL INFIRMARY.

The ordinary drain or "plugging" of folded gauze takes a certain period of time to make. When the gauze is at all hard or its fibre coarse, partially glazed or mercerized, as is notably the case with some of the American gauzes, the difficulty of folding is increased. Machine-made plugging is expensive, and the sizes to hand are not always those required. It occurred to me that at this time, when large quantities of plugging are required for use with hypertonic or other treatment, or for stopping a secondary haemorrhage, it would be advisable to use

some form of cheap lamp-wick, but the woven varieties are rather closely knit, and the twisted varieties are apt to be unmanageable with a probe. Some of the wicks sold do not absorb water.

A simple solution of the problem, apart from constructing a machine for the purpose or adapting a knitting machine, is to utilize a child's knitting reel with which reins or "cats' tails" are made. Three pins to the reel seems to be better than a larger number, but if a more truly circular and tubular wick is desired a larger number may be used. In this case the product is either closer in texture or unduly large. The illustration shows a reel of convenient size, the drain being $\frac{1}{2}$ in. in diameter; other useful sizes are $\frac{3}{8}$ in. and $\frac{1}{4}$ in. in diameter respectively. These three sizes are

made by employing reels of the following sizes in inch measure.

Size of Reel.	Diameter of Wick.		
	$\frac{1}{2}$ in.	$\frac{3}{8}$ in.	$\frac{1}{4}$ in.
Height ...	1	1 $\frac{1}{2}$	1 $\frac{1}{2}$
Outside diameter ...	2	1 $\frac{1}{2}$	1 $\frac{1}{2}$
Diameter of hole ...	1 $\frac{1}{2}$	1	$\frac{3}{4}$
Side of triangle ...	1 $\frac{1}{2}$	1	1
Size of cotton ...	2	4	10

In this table the only important measure is the distance between the feet of the (equilateral) triangle formed by the pins, because on this depends the size of the stitch in the tail. The other measurements merely indicate the sizes of reels convenient to work with. Any reel large enough to take the triangle, and having a hole large enough not to compress the tail will do. Any kind of pin or tack will answer the purpose, but a convenient thing to use is a full gauge, $\frac{3}{8}$ in., brass escutcheon pin, sold by most ironmongers.

The cotton used is Alexander's four-thread knitting cotton (bleached), and the sizes to correspond with reels of the above-mentioned measurements are No. 2 (thick), No. 4 (medium), and No. 10 (thin), the approximate diameters of these threads being $\frac{1}{2}$ in., $\frac{3}{8}$ in., and $\frac{1}{4}$ in. (the latter one *plus*). This cotton is a smooth, loose twist of four strands, which does not tend to fray out, and is lissome and absorbent. Any soft fibred cotton will do, but for each size there is a corresponding size for the sides of the triangle, if one is to obtain a tail of the right body and tension—namely, one in which the mesh is open and the strands do not fall and cling together. The cost at retail price of the cotton mentioned is 1s. 2d. the $\frac{1}{2}$ -lb. hank, for all sizes. Each hank makes:

Of No. 10 (thin), 130 yards of wick; time 36 hours.

Of No. 4 (medium), 42 yards of wick; time 9 hours.

Of No. 2 (thick), 22 yards of wick; time 5 hours.

The thick size is cut into lengths of 6 in. and 10 in., the medium into lengths of 4 in. and 7 in., and the small into lengths of 3 in. and 6 in., the loose clippings removed and the ends caught up into a single knot, or this may be done in the process of knitting, and adds about four hours to the total time for the above-mentioned quantities. The thick variety is more suitable for use as plugging than as a drain, and for drainage one should use two or more strands of the medium instead of one of the thick size.

Convalescent patients or children can readily make large quantities of these drains and thereby save a good deal of the nurses' time at present taken up in folding gauze. There are no raw edges, the mesh is open, and the absorbing power great, partly owing to the choice of material and partly to the size of the stitches. The twist in the cotton produces a high degree of capillarity, and the attraction between the films in the meshes is considerable.

LOCAL TREATMENT OF SUPPURATING SKIN LESIONS AND INFECTIONS.

BY

GEORGE HOME, M.D. EDIN., MAJOR N.Z.M.C.,

SINCE entering upon active service I have been confronted with the treatment of a considerable variety and a large total number of suppurating abrasions, ulcers, boils, and localized infections of the skin. In addition to other unfavourable conditions (for example, heat and dust) my subjects have been mostly unable or unwilling to give mechanical rest to the injured part; these sores have frequently, therefore, been very obdurate.

After several months' trial of permutations and combinations of dressings—wet and dry dressings, with antiseptics and without, antiseptics without dressings, open air, and direct sunlight—with ultimate, but, to my mind, unreasonably slow healing, the following method was arrived at, and for the last three months has continued to prove the most rapidly successful and satisfactory of any. Its only requirements are 3 per cent. cyanide gauze and adhesive plaster, occasionally a pair of scissors, and (for boils) a scalpel. No solution or other antiseptic is used. The suppurating surface is gently wiped dry with a clean piece of cyanide gauze; another piece, only slightly larger than the actual sore and about 6 to 8 ply in thickness, is laid on dry and fixed with strips of zinc oxide or other adhesive plaster, imbricated so as to make a watertight dressing. It is very important to cover the gauze completely, and the thickness of the gauze dressing varies with the amount of probable discharge. This dressing may be left untouched for one, two, three, or four days, according to indications. If comfortable, with no lymphatic evidence of absorption, the less often it is disturbed the better. Subsequent dressings are done exactly in the same way as the original.

A corporal came to me with a suppurating sore, 2 inches square, on the back of the left wrist, which had refused to heal for three weeks. I wiped it clean with cyanide gauze, making it bleed slightly. There being no water or solution handy I put a piece of dry gauze on it, covered it carefully with adhesive plaster, and told the man to report

next morning. He did not return until four days afterwards. The dressing, which had not been disturbed, came off easily, the sore was perfectly covered with a soft bluish-white skin, and there was no further trouble.

Reflection on this result led me to the conclusion that this form of dressing (1) gave the best surface protection to the damaged part, (2) contained sufficient mild antiseptic to inhibit further bacterial growth on the skin surface, (3) allowed of the production and maintenance of bactericidal and healing serum locally in the sore, and (4) that for this last reason it was important neither to wash the part nor to put the gauze on wet. Such procedure would have spoilt the biological properties of the serum, and would have interfered with the nourishment of the healing cells, especially if any stronger antiseptic had also been used.

It is important to cover the gauze completely with the adhesive plaster—firstly, to give accurate fixation and mechanical protection, and secondly, to retain in the gauze moisture sufficient to keep the serum at normal consistence and to prevent the dressing sticking to the raw surface.

It is, of course, necessary to get the whole infected area completely exposed for the dressing—that is, to remove all crusts and scabs and overhanging cuticle, as in suppurating blisters. At first I felt impelled to use a touch of surface antiseptic (iodine tincture), but a parallel series of tests of similar cases convinced me that it was better not to annoy the sore. I also have a conviction (perhaps begotten of theoretical considerations) that a covering film of fresh blood on the sore is an initial advantage.

Applying a similar principle to boils, I open each, whatever its stage, with a Paget's knife, taking care to cut into the induration also; gentle pressure is applied to get out only what pus will come easily; the surface is dry-wiped and then dry-dressed exactly as already explained, preferably with a film of fresh blood over the boil. At first the gauze pad is made fairly thick and, if there is much pus, renewed twice a day. There is very little pain after the initial dressing and the core usually comes out on the third or fourth day. Before the first and after the last dressing I paint the skin for some distance around the boil with iodine tincture to diminish the chances of spread of local infection.

My subjects are vigorous young New Zealanders on active military service, whose blood and tissues are therefore very capable in the production of antibodies. But I consider that the idea might be applied to chronic ulcers, to so-called "eczemas," and to other suppurative and exudative skin lesions met with in ordinary practice.

It is therapeutically sound to let bacteria "stew in their own juice" when conditions permit, and it is quite easy for a small wrong detail in treatment to upset the quality or quantity of the "juice" and to spoil its capacities both for devitalizing the infecting agents and for vitalizing the repairing agents. This spoiling may be done by diluting it or by desiccating it.

The middle course is Nature's own. She puts a dry hard scab on a healing sore that just sufficient fluid may collect under it to nourish the healing cells, and give it a tight hold that cannot be disturbed without disaster before healing is complete.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

COMPRESSION OF AORTA IN POST-PARTUM HAEMORRHAGE.

On the night of October 28th I was called to a 2-para, aged 28, who had been three or four hours in labour. Her first labour, three years before, had been terminated with forceps under chloroform. The os was completely dilated and retracted, and the head about half through the brim. The pains were strong and frequent, but little, if any, progress was made during half an hour.

I put her under chloroform, using Duncan and Flockhart's, by the open method, but not to the surgical degree, applied Simpson's long forceps, and delivered, with comparatively little difficulty, a living baby. The uterus

contracted well under manual pressure, but as I failed to express the placenta by the Dublin method, and as distinct pulsation in the cord indicated adherent placenta, I introduced my left hand—well asepticized—and found a small surface adherent right up at the fundus. This I separated easily, and brought away the placenta in front of my hand. I compressed the uterus manually for some fifteen minutes until firm contraction resulted, and then proceeded to wash my forceps and hands. In ten or fifteen minutes the nurse called to me and I found the uterus much distended; I expressed a regular torrent of blood, and massaged the uterus till firm contraction resulted. I made the nurse keep up the manual pressure while I gave a hypodermic injection of ergotinine citrate (1-200 gr.), and then proceeded to compress the abdominal aorta against a lumbar vertebra in the "crutch" formed by the flexed index and second fingers of my left hand, the arm being fully extended, and made the pressure absolute by the tips of the two corresponding left fingers against a lumbar vertebra close to and in front of the right. The aortic pulse was feeble, irregular, and intermittent, the patient lying in a faint with lips and surface white and exsanguine. I had sent for Dr. Hutchinson to give normal saline, and he instilled about 8 or 10 oz. into the areolar tissue beneath each breast. I kept up pressure till the patient rallied, and in about half an hour gave her some warm milk; I stayed another half-hour, but there was no return of haemorrhage.

The patient recovered without a single bad symptom, suckled her baby, and resumed her household duties in twelve days, but I am morally certain that the compression of the aorta was the chief factor in saving her life.

East Ham.

C. STENNETT REDMOND, M.D.

FOREIGN BODIES IN RECTUM.

THE following case is of interest, owing to the fact that it was the second occasion on which the patient had swallowed the foreign bodies, and, in my opinion, they had not been introduced from below. The patient, a female aged 19 years, not pregnant, informed me that she was suffering from constipation and had taken purgatives, but with no definite result, chiefly due to pain in the rectum during the act of defaecation. I gave her calomel gr. v, and directed her, if it had not the desired result, to remain in bed and send for me. The next day I was called to her house, and, before examining her, I elicited the following history. The bowels had not moved for fourteen days; she had swallowed during a day and night, about fourteen days before, two full boxes of wooden matches (safety). I was amazed to be told by her that I would require to give her chloroform and remove them from the rectum, as a doctor had had to remove them in that way before. On examining the rectum with the finger I found it full of matches lying in all directions as far as my finger could reach; the finger when withdrawn was covered with blood due to the excoriations of the mucous membrane by the sharp end of the matches. I removed the matches—of which there must have been at least two boxes—after consideration, without an anaesthetic, as a moral lesson to the patient not to swallow highly indigestible substances in future.

Winchburgh.

JOSEPH STARK.

IMPERFORATE HYMEN AND ABSENCE OF UTERUS.

I PUBLISHED a "case of complete atresia vaginae and absence of uterus" in the BRITISH MEDICAL JOURNAL of October 5th, 1901, and as such conditions are extremely rare, it is a singular coincidence that I should have met with another somewhat similar condition.

A girl, aged 18, was brought to me by her mother because she had never menstruated. She is a perfectly healthy, strong, and well-developed girl. I found an imperforate hymen. Examination under chloroform at the hospital revealed a strong thickened hymen, but the uterus was completely absent, although a thin whipcord extended from side to side of the pelvis.

Mirfield, Yorks.

LESLIE J. MILNE, A.M., M.D. Aberd.

Reports of Societies.

TREATMENT OF SYPHILIS.

At a meeting of the Association of Registered Medical Women on December 14th, 1915, Dr. HELEN BOYLE in the chair, Dr. MARY SCHARLIEB, in opening a discussion on venereal disease with special reference to syphilis, said that the difficulty in obtaining treatment in the early and hopeful stages was due to a twofold plea—(1) that it tended to encourage vice; (2) that funds intended for the relief of the innocent sick were used. Many sufferers, especially women and children, however, were entirely innocent; the expense of treatment and maintenance in the later stages was infinitely greater, and untreated syphilis might spread the infection. The recognition and treatment of syphilis were now assured facts since the introduction of the Wassermann test and of salvarsan, so that the excuse of prolonged and uncertain treatment no longer held good. Since salvarsan could no longer be obtained, kharsivan made in this country, and galyi, manufactured in France, had been found reliable. With regard to infantile mortality, investigation showed the number of cases of syphilitic infection—pre-natal and post-natal—to be great. As many children died in the six months before birth as in the first twelve months after birth, and the great majority of intrauterine deaths from the third month onwards were due to the *Spirochaeta pallida*. From evidence given before the Royal Commission on Venereal Diseases the most satisfactory form of treatment appeared to be as follows: The diagnosis having been established, either by finding the spirochaete or by the Wassermann test, salvarsan or one of its substitutes was injected intravenously; this was followed by inunction of a mercurial cream for ten weeks. A second intravenous injection of the arseno-benzol compound was then given, followed again by inunction for ten weeks; and both were repeated a third time. After this the Wassermann test should be repeated at intervals for two years. Dr. MARY JOHNSTONE said that in asylums the treatment of cerebro-spinal syphilis, if diagnosed early, was successful, that of general paralysis of the insane and tabes difficult, though injection of salvarsan relieved the lightning pains and gastric crises. It had to be remembered, however, that remissions occurred in general paralysis of the insane even without specific treatment; some patients were discharged as cured, but all died suddenly within a few months. Dr. KATE ADDISON said that statistics collected in skin departments showed that from 1.5 to 2 per cent. of the cases coming for treatment were syphilitic. Among 500 cases at the skin department of a children's hospital she had found no case of syphilis. Dr. HAZEL CUTHBERT described a case of possible delayed congenital syphilis in a boy aged 9. There was oedema of legs and face and intense ascites without albuminuria. The Wassermann test was positive. Dr. ELEANOR LOWRY, in speaking of syphilis of the throat, nose, and ear, said that syphilis, unlike tuberculosis, usually commenced in the epiglottis. Atrophic rhinitis was not as a rule syphilitic in children between 7 and 12. Secondary labyrinthine deafness with nystagmus and vertigo cleared up with antisyphilitic treatment, but congenital nerve deafness was generally incurable. Dr. HELEN WILSON said that the system of registration, which had been in vogue for 100 years, was unjust, unscientific, and unsuccessful. Early and efficient treatment was essential. Notification, though theoretically good, was not practicable. The Danish system of free and compulsory treatment had not diminished the incidence of the disease. Rather than apply compulsion to the unwilling it would be better to provide fully and helpfully for willing patients. Dr. ELIZABETH COURTAULD said that at the Lock Hospital three intravenous injections of salvarsan or its substitute were given at a fortnight's interval, and mercury was given by intramuscular injection and not by inunction. Mercury caused a remarkable increase in weight; one patient gained 7 lb. in a week. Mercurial treatment was continued for seven years. Kharsivan had been considered poisonous, but out of 96 cases treated, 84 had shown no reaction, 11 a slight reaction, and one a reaction up to 102°.

Rebels.

THE ANTIQUITY OF MAN.

THE purpose and scope of Professor ARTHUR KEITH's new book are well indicated in its title, *The Antiquity of Man*.¹ In it the evidence which tends to put back the time of man's first appearance to a period much earlier than was until recently by any one supposed possible is examined and pronounced valid, but the contention which gives its special character to the book is that modern man, or at any rate, man with a brain case as capacious as the average of to-day, or even larger, existed in the middle pleistocene epoch, probably earlier. This may be said to be the purpose of the book. Its scope is very wide, for in the process of examining the evidence every specimen is described, in most instances very fully, and the conditions under which it was found discussed. This involves the study, first, of the evidence as to the authenticity of each specimen—some, owing to lack of accurate and trustworthy records, are under grave suspicion, or have to be rejected; secondly, of the geological evidence as to the probable age of the stratum in which the specimen was found; and thirdly, of the evidence afforded by the remains of animals found with the specimen, and of the character, whether less or more primitive, of the stone implements believed to be of the same epoch. A fourth line of evidence is afforded by the more or less primitive anatomical characters of the specimen, but the nature of Professor Keith's thesis in, roughly, the first half of his book, to some extent shuts him out from using it as evidence of antiquity.

This thesis is that modern man, modern in the form and capacity of his cranium, existed as early as the Neanderthal type, from which it has been assumed that he was evolved. Professor Keith does not now hold the view that Neanderthal man is in the ancestral line of modern man. He agrees with Dr. W. H. Duckworth that the race (or species) became extinct, and believes that it branched off at some early period from the stem from which modern man evolved; it took the wrong road and failed.

The general plan of the book is to recount the circumstances in which each specimen was found and its geological relations, to describe very fully its anatomical characters with the help of diagrams of the skull set within a framework of lines which bound the chief diameters of a modern skull of mean size, and finally to sum up the evidence, as to authenticity, antiquity, and anatomical characters. In this way we are taken through the stories of the long series of discoveries from those of

¹ *The Antiquity of Man*. By A. Keith, M.D., A.B.D., F.R.C.S. Eng., F.R.S. London: Williams and Norgate. 1915. (Demy 8vo, pp. 529; 169 figures. 10s. 6d. net.)

Neolithic men in this country, probably the contemporary of the pre-dynastic Egyptians, to Piltown man (*Eoanthropus Dawsoni*), who lived either in the early Pleistocene period as Dr. Smith Woodward believes, or, as Professor Keith thinks, even earlier—that is to say, in the Pliocene period. As to the actual date, it may be a quarter of a million years ago or half a million, but probably nearer the latter than the former, perhaps a million. This is a very wide margin, but the date, and even whether *Eoanthropus* was Pleistocene or Pliocene becomes of less importance if we accept the view which has the support of Sir E. Ray Lankester, that the subcrag flints of East Anglia and the eoliths of Kent are man-made, for then the beginnings of man must be put back to a geological period antecedent even to the Pliocene.

It seems that the school of thought which maintains that the modern type of man and the Neanderthal type existed on the earth together have proved their case, and have made it probable that the former expelled the latter from Europe, supplanting him so completely that the beetle-browed man became extinct. If it be admitted that the two types were contemporaries the consequences, as Professor Keith points out in a concluding chapter, are very far-reaching. He illustrates them by a genealogical tree from which we have made the accompanying simplified sketch. If, somewhere in the middle Pleistocene two types of men existed as different as Modern man and Neanderthal man, the fact argues a long antecedent period of evolution, long enough for the human stem to have branched into at least these two divergent types, and perhaps a third—*Eoanthropus*. Parity of reasoning puts back very much further the period, perhaps two million years ago, when the human stem separated from that which in the process of evolution has yielded the anthropoid apes and the gibbons. We are, in fact, confronted with another question—namely, when, if we ever have a complete tree, should it be said that the creatures in the human stem become endowed with brains which entitled them to be called man? For we must assume that the bigger brain preceded the skeletal changes.

Professor Keith has written a book of extraordinary interest which makes its appeal to the already large and, we believe, rapidly growing section of the public, who want to know how science is moving and to what ends, and is not satisfied to take its information at second hand, but wishes to learn from the expert. The book is one which only an accomplished anatomist could have written; it is full of anatomical facts and discussion. So far, therefore, the medical reader is in a better position to follow the argument than others, and it is very much to be commended to medical readers for several other reasons. One is that the enthusiasm of the author infects the reader, who at the same time has the conviction that the facts are recorded with scientific conscientiousness, even though the hypotheses founded on them may not always carry complete conviction. That this is the case Professor Keith freely admits when he says in his preface that he is convinced that the true solution cannot differ materially from that presented in the diagram here given, but that it "is only one of many [solutions]; time will show which is right." Another reason is that some of the most important finds have been due to the vigilance of amateurs who have closely watched excavations, even in such unlikely places as the small pit used by the farmer at Piltown to get gravel to mend his cart road. How many other fragments of fossil man have been used to mend the roads elsewhere no one knows, but the medical reader of Professor Keith's book will learn to look on gravel pits with a more discerning eye than heretofore. A final reason is that the book lifts its reader out of the obsession of the war, and may help those inclined to despair of humanity to take a longer and, let us hope, a truer view.

The book is very well illustrated, by which we do not mean only that the number of illustrations is large—the list enumerates 189, many of them consisting of more than one drawing—but that each really elucidates the statements or arguments in the text, and all appear to have been specially drawn for the book by Dr. Stanley Beale and Mr. William Finerty. The publishers deserve a word of praise for the pains taken to get each drawing in or very near the place where it is discussed and described, but they ought to have supplied a better index and may, we hope, yet do so in another edition.

PUBLIC HEALTH.

*English Public Health Administration*² is one of the series of studies in economics and political science issued under the direction of the London School of Economics. In his preface the author, Mr. BANNINGTON, states that the aim of the work is to provide a survey of the methods of public health administration, and thereby fill a gap which has heretofore existed, since public health literature has concerned itself only with either purely formal statements of Acts of Parliament supplemented by annotations and comments, or with the practical application of technical knowledge. In this he has been successful. The work is an exceedingly useful addition to the literature of public health, and will be most helpful to those who, having entered the public service possessed of a general knowledge of the statutes, are admittedly ignorant of the application of legal powers to local and special conditions. The lucidity with which the author has treated an intricate subject is very creditable, and certain criticisms and strictures will be heartily endorsed by those who have experience of the use of an imperfect machine, complicated by additions and crippled by gaps. The desire of the author to have a great consolidating and simplifying Act, which would abolish the riot of Acts of general application, adoptive Acts, private Acts, orders, by-laws and regulations, is one common to all concerned in the administration of public health departments. Difficulties are, however, put in the way of such consolidation by the fact that health problems are largely governed by scientific and social investigations which are still incomplete, and that experience concerning the proper functions of county councils as opposed to borough and district councils is still immature. Few, if any, public health officials will disagree with the author's strictures on private slaughter-houses. It can be positively asserted that the loose way in which the public meat supplies are supervised is a menace to national health, owing to the defective legislative control of premises where nefarious acts can be conducted with little risk of detection. The chapter on finance is to be especially commended. It is a clear exposition of a subject still for many public health officials shrouded in mystery. We thoroughly agree with the passage in the work devoted to security of tenure of sanitary officers. The capricious attitude of some local authorities towards their officials is well known, and existing so-called security of tenure may mean little. In that part of the work devoted to a discussion of the staff, the reactionary suggestion is made that the administration should be duplicated, the one department being that of the medical officer of health, and the other that of the sanitary inspector. Efficiency in any municipal department can be obtained only where there is one chief official—the chief of the public health department must be the medical officer of health. The work of the sanitary inspector is concerned with the control of conditions inimical to health, and that statement, which none can dispute, is sufficient to convince any impartial person that the final departmental consideration of such conditions must lie with the medical officer.

THE CANCER PROBLEM.

INTO his book on *The Cancer Problem*³ Dr. W. S. BAINBRIDGE has collected notes on practically every piece of work on cancer published within the last ten or fifteen years. He has been a studious reader of everything connected with cancer, and he has travelled much in Europe, visiting most of the clinics and laboratories where cancer research of any description has been done, gaining opinions from individual workers of their own work, and undoubtedly criticisms of the works of others. Much of the work and many of the opinions are of ephemeral value, some, perhaps, may be landmarks in the history of the research, but whatever has been done or said—good, bad, and indifferent—finds a place in the pages of the book. There is very little discrimination attempted by the author, and no one not conversant with the subject would be able to winnow the wheat from the chaff, but the book

² *English Public Health Administration*. By B. G. Bannington. Introduction by G. Wallas, M.A. Studies in Economics and Political Science, edited by the Hon. W. Pember Reeves, Ph.D., No. 46. London: P. and S. King and Son, Ltd. 1915. (Demy 8vo, pp. 349. 7s. 6d. net.)

³ *The Cancer Problem*. By W. S. Bainbridge, A.M., Sc.D., M.D. New York: The Macmillan Co. 1914. (Med. 8vo, pp. 552; 28 plates, 12 figures. 17s. net.)

serves as a fairly orderly summary of the main papers that have been published down to the time of its publication, and the student may find it a convenient place in which to look for an account of researches that otherwise would be difficult to unearth from bibliographies.

NOTES ON BOOKS.

THE tenth edition of Mr. T. W. SANDERS'S *Roses and Their Cultivation*¹ is well illustrated by pictures in colours and in the text. By the inexperienced it will, perhaps, be most appreciated for its directions for pruning, which are well illustrated by very clear diagrams. The chapter on the diagnosis and treatment of diseases of roses is also very practical, but the book suffers for want of a better index. There is a very copious and useful table of varieties, giving the date of their introduction and short notes on their character and peculiarities, but without more knowledge than an amateur newly taking up rose-growing can be expected to possess he may have some difficulty in finding what he wants.

In the collection of papers by the late Canon BARNETT and Mrs. BARNETT, under the title *Practicable Socialism*,² we have brought before us the chief points of the work begun in St. Jude's parish during the years that Canon and Mrs. Barnett laboured there. We are familiar with their desire to give education—that is, a wider use of eyes and ears, and a wider capacity for enjoyment—and cordially agree in the need for hobbies. Many of the suggestions made years ago have become realities now, such as vacation schools, travelling parties of schoolboys and schoolgirls; but many suggestions, notably in connexion with the welfare of the children of the State, need further development. The book should be read by those interested in the lives of their poorer neighbours.

A liberal selection from the works of British poets, from Chaucer to Thomas Hardy, has been made by Mr. BEAUMONT, and published at a wonderfully cheap price by Messrs. Jack.³ It contains, we are told, nearly 60,000 lines; it embraces both lyrical and non-lyrical poetry, excluding only the dramatic. Great care has been taken to employ trustworthy texts; a glossary for Chaucer and the Scottish poets has been provided. Poetasters as well as poets are represented in the selection; the paper and printing are excellent. The book may be cordially recommended to the patronage of the general reader.

MOTOR AMBULANCE DEVELOPMENT.

By H. MASSAC BUIST.

WHILE the French persevere continue to use all manner of vehicles for motor ambulance work, mostly of varieties quite unsuitable for it, as far as our endeavour at the front is concerned, the British Red Cross organization has settled down to the use of thoroughly standardized types of ambulances; therefore we are getting what are really remarkably satisfactory results now that the variety of types and makes has been reduced to the minimum, and that the chassis, as well as the ambulance bodies, are modern in design.

While it has not been eliminated, nevertheless overhang has been enormously reduced, and suspension vastly improved. When wounded may have to be dealt with by the thousand, and in a race against time, the motor ambulance must of course continue to be a machine of the compromise sort.

It is rather in those varieties which are being acquired for service at home that one sees new ideas tried out nowadays when we have other things to do than experiment at the front. For example, one of the latest additions to the Hampshire Automobile Club's fleet of ambulances is equipped with a body designed by Captain R. W. D. Leslie and Captain G. A. Child, both of the R.A.M.C., as the result of their experiences in removing the wounded. The coachwork has been carried out by the Southampton coachbuilding firm of Andrews Brothers. The body is fashioned of three-ply wood, and is canvas topped, there being four hopper windows on each side, such as are often used in hospitals, which when opened allow air to enter

only in an upward direction. The driver is completely protected by a canvas cowl and side curtains, to which hopper windows are also furnished. The communicating door folds back over the driver's seat, and is furnished to enable orderlies to pass through into the interior of the car. This door has a ventilator and a window. In hot weather it can be left open. A padded collapsible seat is provided in the gangway for the orderly in attendance, and he has ample room to attend to the patients occupying each of the four cots. The locker containing medical requisites is ingeniously accommodated over the driver's head, the entrance to it being in the interior of the ambulance.

In thirty seconds both sides of the interior can be converted from accommodating lying down to sitting cases, for which latter ample leg room is provided. An ingenious use of levers, whereby the seats are automatically raised into position as the lower stretcher trays are folded back, eliminates the fault of low seats for this service. This and the excellent padding arrangements are features of design too generally overlooked in a war in which the majority of the wounded to be transported are sitting cases. One ingenious weight-saving contrivance, which besides ensures the step being up when the car is loaded, is that whereby the tailboard, when lowered, forms the step at the rear of the ambulance. The back doors are detachable and can be folded against the sides of the ambulance, so that in hot weather the whole of the back is open.

An interesting contribution to the trailer-ambulance problem is brought forward in the ambulance-caravan trailer designed by the Steel Trucks Company, of 18, College Street, Lambeth, designed to be capable of being run up to thirty miles an hour with comfort to the passengers as a trailer to any motor vehicle, and to be produced at a cost of £150. Tubular steel is largely used in the construction, the aim being lightness combined with rigidity. It accommodates four stretcher cases and can be converted to take sitting cases. The top end of the vehicle is furnished with a tank for water. Arrangements are also made for fitting, as an extra, an acetylene cooking apparatus with all facilities for cooking for twelve persons. The standard equipment also provides space for rifle lockers and for men's kits. When the four Government regulation stretchers are in position there remains a 17-in. gangway for the orderlies.

Good work has been done lately by the Scottish branch of the Red Cross Society in providing a number of motor ambulance boats for service in the East.

MEDICAL CARE OF SCHOOL CHILDREN.

THE annual report for 1914 of the Chief Medical Officer of the Board of Education¹ surveys the whole field of the preservation of child life and the care of the health of school children.

THE SCHOOL MEDICAL SERVICE.

The work of the service has been seriously affected by the war. Doctors and nurses have been taken away from the service of the children to that of the fighting men. The report states that so soon as the requirements of the army were known, the board gave every facility for the arrangement of the work that would facilitate the freeing of as many of the medical staff as possible. The board issued a circular intimating what part of the school work was in its opinion essential and should be regarded as a first charge on the time of the school medical staff, and stating that the board would continue to pay grants at the present rate in relation to expenditure in all cases where the arrangements made were in the board's opinion reasonably satisfactory, regard being had to all the circumstances. The intimation of the Local Government Board that all fresh expenditure was to be curtailed has checked the progress of new work; various proposals for the establishment of school clinics, for example, have been stopped on this account.

What loss the school medical staff has sustained owing to war conditions the report does not state. But at a recent meeting of the Central Medical War Committee

¹ *Roses and Their Cultivation*. By T. W. Sanders, F.L.S., F.R.H.S., etc. Tenth edition. London: W. H. and L. Collingridge. 1915. (Post 8vo, pp. 213; 39 plates, 54 figures. 3s. 6d. net.)

³ *A Book of English Poetry*. Chosen and edited by G. Beaumont, M.A. London: T. C. and E. C. Jack. 1915. (Med. 8vo, pp. 583. 3s. 6d. net.)

¹ The Annual Report for 1914 of the Chief Medical Officer of the Board of Education. London: Eyre and Spottiswoode, and Wiman and Sons. 1915. (1p. 309, price 1s. 3d.) [Cd. 8055.]

information was given that out of a total medical staff of 1,234 doctors in England and Wales, a total that includes men over military age and women, no fewer than 304 were on military service. That is a goodly number, but it is probable that at the present moment it is larger. The value of the work of the school medical service in times of peace is undoubted, and its influence on the national well-being incalculable. To this must now be added the value of this staff as a reserve of doctors who may be called upon for national service in an emergency.

The institution of special researches by the school doctors has been urged on many occasions. For this year Sir George Newman suggests that the subject for inquiry should be "Malnutrition." The subject is well chosen, for it would appear that there is more money in the hands of the working class population at this time than ever before; under these conditions it will be of particular interest to observe the effects of this increase of income, and we should hope of better feeding. Certainly the demand for school feeding has diminished. Certain points in the production of malnutrition are of special importance, for example, antenatal conditions; social conditions, such as housing, and the non-domestic employment of the mother; and the employment of children out of school hours. During last year no fewer than forty-two investigations were made by various school doctors on special conditions relating to the schools or of particular sections of the children; a list of these researches is given on page 8 of the report.

Certain points in the working of the medical arrangements are considered. "Following-up" of cases reported for treatment is one of special importance. It is noted that nurses are now required to visit the home of the child to advocate home care and medical treatment; these visits are of particular value in the crusade against uncleanness. The value of Care Committees, of the work of the teachers, and of school attendance officers is noted in this connexion. In London alone there are 1,000 Care Committees; their work is spoken of with much appreciation. The teachers' influence on the side of health is remarkably efficient. There was a time when the entry of the school doctor was resented as a general nuisance, one more unnecessary inspection, and in particular an infringement on the complete and indivisible authority of the pedagogue. Those ideas have gone, and with a surprising rapidity, for the teacher speedily learned that the work of the school doctor was all to his or her advantage. We must look to this interest of the teacher to carry on the work of school medical inspection in some part during these troublous times. The work of the doctor must be of necessity limited to matters of strict urgency, and this must needs demand the cessation of much of the routine medical inspection. The modern teacher can to some extent fill the gap; he has learned that dullness on the part of the child is not to be regarded as a natural folly bound up in the heart of the child, needing only to be driven forth with the rod of correction; he now knows that these difficulties commonly spring from physical disabilities which are frequently remediable by medical art; and we may look to the intelligent teacher to report these cases when they can no longer be sorted out by the regular use of the normal machinery.

Note is made of the increasing tendency to provide medical inspections in the secondary schools. There is no statutory requirement that this should be undertaken, but its manifest advantages cause the system to spread.

Note is also made of the duties arising out of the Mental Deficiency Act of 1913, the necessity for ascertaining what children are defective within the meaning of the Act, and the possibility of their mental improvement under education. Excluding imbeciles and idiots, it is considered that the number of educable mentally deficient children does not materially exceed 25,000. The number of certified schools for these children is 184, providing accommodation for 14,555 children, and having a total average roll of 13,563 children. Of these, 11 schools are residential, accommodating 902 children. The figures of the estimated number of children to be provided for and the available places indicate that increase in the number of these schools will be necessary in the future. It is undesirable, both in their own interest and in that of the normal children, that these children should drift on in the elementary schools. When there is doubt as to the educability of the child there is power to refer the case to the Board of Education medical authority. It will be of

interest to have some report on the working of this provision. At present it does not seem to have been used to any great extent, but from evidence at our disposal it would appear that with the increasing difficulty in getting cases certified as ineducable there is a tendency to let all cases, save those of the manifestly imbecile, go in default. This would not be a satisfactory conclusion of the policy of check and counter-check in certification.

EDUCATION AND INFANT WELFARE.

"The Board of Education are responsible for bringing educational influence on the problem of nurture." The education of the child needs a healthy child; medical inspection, care, and treatment are natural corollaries, and there follows the inevitable necessity to bring influence to bear on the beginnings of the child, and particularly as those are affected by external surroundings and conditions. "The environment of the infant is its mother." In that saying is the justification of the recent extensions of the work of the education authority.

In 1914 no fewer than 93,166 children died in England and Wales under 1 year of age; the infant mortality rate was 105 per 1,000. That is the lowest rate for the last ten years with one exception. The chief post-natal causes of infant mortality are three: (1) Epidemic diarrhoea and enteritis—due mainly to bad feeding. (2) Immaturity and congenital defects—due it is thought in part to poor maternal physique or disease. (3) Respiratory disease—attributed to exposure, cold, and infection. Comparing the incidence of death in town and country it is manifest that with all our modern improvements the town is a bad place for the child. In ninety-seven great towns including London the death-rate was 114 per 1,000, in 145 smaller towns 104, in the rest of England and Wales 93. Even in great cities similar differences can be found. In Shoreditch the rate was 141, and in Bethnal Green 137, whilst in Chelsea it was 67, and in Hampstead 80. "It is obvious, therefore, that urbanization, with all its means of overcrowding, tenement housing, employment of women, domestic insanitation, etc., is exerting indirectly a profound effect on the health of young children." Sir George Newman concludes by stating that "the principal operating influence is the ignorance of the mother, and the remedy is the education of the mother."

The health of the child on entry to school, between the age of 3 and 6 years, points the same moral. For the most part the incidence of defects is much more heavy in the town children. Uncleanliness of body sometimes reaches the high figure of 12 to 15 per cent., and in certain districts still higher (Brighton 23 per cent., Bilston 37). Uncleanliness of the head varies from 15 to 20 per cent., but some districts are very bad (Mansfield 44). Rickets is found in from 1 to 3 per cent.; in some urban areas it is as high as 5 to 8 per cent. Eye diseases such as conjunctivitis and blepharitis run up to 10 to 12 per cent. in some large towns and at certain times. Diseases of the nose and throat vary widely, and are by no means always most prevalent in town children. Malnutrition in the counties varies in percentage between 5 and 20; the figures given for eight large north country towns vary from 16 to 30 per cent. It is held that these high rates are in many cases the effects of the same conditions that take such heavy toll in death. So that both the death-rate and the state of the infants when first brought to school point to the necessity for the education of the mother.

Four educational methods exist to this end—schools for mothers, day nurseries, nursery schools, and the training of elder girls.

(To be continued.)

MR. CHRISTOPHER WELCH has left his real estate in the county of Somerset to the University of Oxford for the endowment of scholarships for the study of biology, to be known as the "Welch" scholarships. They are to be tenable for four years and their total value is to be £400 a year, any surplus income to be paid into a reserve fund formed by the residue of his estate, to be used for the upkeep of the estate and for furthering the study of biology. If the university does not accept the conditions attached to the bequests, then the amount goes to six London hospitals, one of which shall be St. George's Hospital; but no hospital where vivisection is disallowed or discountenanced is to benefit; "antivivisectionists being enemies of the human race."

British Medical Journal.

SATURDAY, JANUARY 1st, 1916.

THE BRITISH MEDICAL ASSOCIATION IN 1915.

THE WAR.

IN time of stress, such as that through which we are now passing, it behoves all societies, associations, or other bodies of men, no less than individuals, to ask themselves the question, "What help can we give to our country?" The issues involved in this war are so many and serious that no one can be excused from rendering assistance in accordance with the means at his disposal. Thus it came about that quite early in the conflict the question thrust itself insistently on the minds of those responsible for the conduct of affairs in the British Medical Association, and led to action. At first this action was tentative in character, as might be expected when men had not yet recovered from the stunning blow caused by the sudden onset of the war. It consisted of little more than an offer to the War Office of all the assistance in the Association's power, the lending of some clerks to the overwrought British Red Cross Society, and the practice of certain economies in the domestic management of the Association itself. Committee meetings, for example, were reduced in number, and the meeting of the Council in October was abandoned. Early in August the Chairman of the Scottish Committee of the British Medical Association (Dr. Hamilton of Hawick) summoned a meeting to consider what steps should be taken to meet the medical difficulties arising from the war. At that meeting it was arranged to invite the presidents of the medical corporations of Scotland, the deans of the faculties of medicine in the four Scottish universities, the Scottish members of the General Medical Council, and the members of the Scottish Committee of the British Medical Association, to hold a meeting to consider further action. As a consequence of this meeting a committee was appointed representative of the various bodies mentioned, which issued a memorandum, and later on a detailed statement giving advice on the general principles which should be followed in making arrangements for the carrying on of the practices of those members of the profession who are serving with the King's forces. In this country also schemes were drawn up locally, the earliest of which was that adopted at Southampton on August 4th, 1914, and other Divisions of the Association followed suit, the purpose of the schemes being to put into force means of safeguarding, as far as possible, the practices of Territorial medical officers called up for service, or of those civilian practitioners who took temporary commissions. It was not long, however, before the possibilities of further work by the Association began to be discussed, and in September, 1914, the Army Medical Department was approached with a suggestion that, inasmuch as the majority of those who volunteered for service would be unacquainted with the details of medical military routine, some form of elementary instruction in their future duties might be organized. From this suggestion arose naturally the idea of grouping men in various classes according to

the likelihood of need for their services. But at that time, when nothing more than an army of a million was in contemplation, the War Office was content with the position as regards the supply of medical officers, and considered that the 4,000 or 5,000 offers of service which it had received would amply meet all demands.

In January, 1915, the Council of the Association met for the first time since the outbreak of war. It was then recognized that the continued drain upon civil practitioners in England and Wales would need more careful watching than it had previously received. Consequently the work of dealing with problems arising out of the war was delegated to a committee, already in existence for other purposes, consisting of the Chairmen of the Standing Committees of the Association. To this Committee came the first definitely large demand made by the Director-General in consequence of the magnitude of the requirements resulting from the Dardanelles expedition. At the end of March the profession was asked to supply 2,000 more medical officers to the army; and thus began the co-operation between the Army Medical Department and the British Medical Association, which has since developed into close association. By July considerably more than half the required number had been obtained, and in many localities special steps were being taken. The Council of the Metropolitan Counties Branch, for example, having become impressed by the necessity for better organization of the medical profession in order to meet the requirements of an army infinitely larger than ever thought of in the earlier stages of the war, and recognizing that in the area of the Branch there must exist quite a large reserve of men who could be spared for military service, appointed a special Committee to organize the profession in London and the surrounding areas. Hence arose the first attempt at a register of men of military age fit for service, and the formation of local committees to supply information to the Committee of the Branch.

It was felt, however, that something more than a purely British Medical Association organization was required. Accordingly, it was proposed at the Representative Meeting in July that a special committee more national in character should be formed, including men who could represent the views of universities and other teaching or controlling bodies, no less than those of various types of practitioner. Thus was formed the Committee at first known as the "War Emergency Committee," and now entitled the "Central Medical War Committee." The reference to this Committee was "To organize the medical profession in such a way as will enable the Government to use every medical practitioner fit to serve the country in such a manner as to turn his qualifications to the best possible use; to deal with all matters affecting the medical profession arising in connexion with the war; and to report to the Council."

At his first interview with the Central Medical War Committee the Director-General put forward a request for 2,500 more medical officers, to be obtained before the middle of January, 1916. Possibly in making this request the Director-General had in mind the developments which have since taken place in the Balkans. The request was a large one, and called for strenuous effort; so that from the outset the first duty of the new committee was that of recruiting officers for the R.A.M.C. In furtherance of this work the War Register was completed for the whole of England and Wales; communication was established with the Scottish Medical Emergency Committee, which had already done much valuable work; and

every assistance was given towards the establishment of a similar committee in Ireland. With a view to close co-operation a representative has been nominated by both the Scottish and the Irish committees to serve on the Central Medical War Committee, which meets and has its offices in the house of the British Medical Association in London. Local Medical War Committees have been appointed by the practitioners of all but two or three areas throughout the country through the agency of the Association. To these committees any medical man can refer in his difficulties, while from them the Central Medical War Committee draws its information as to local needs and the ability of a district to supply more officers to the R.A.M.C.

In order to ensure rapidity of action and due preparation of every question for discussion by the full committee an executive subcommittee has been appointed, which meets at very frequent intervals, and confers with representatives of Government departments and other interested bodies. Thus close relations are being maintained not only with the War Office, but also with the Local Government Board, the Insurance Commissioners, the Board of Control, representatives of hospitals, and panel committees, as well as with the local Medical War Committees. When Lord Derby's recruiting campaign was started, it was recognized at once that the medical profession was not suitable ground for such efforts at voluntary enlistment. The Director-General and Lord Derby were approached, with the result that a statement was issued to the press whereby the recruiting of officers for the R.A.M.C. was left entirely in the hands of the Medical War Committees. Information has been given to all local committees describing the manner in which this recruiting problem should be dealt with. Quite recently the Committee for Scotland has issued a memorandum, reproduced in the SUPPLEMENT for this week, in which the details of the machinery are very clearly described.

As the result of interviews with certain Government departments, much has been done in the way of curtailing clerical work and setting free as many medical officers as possible for service. Valuable information has been received from the Insurance Commissioners with regard to areas in which there may be a possibility of undue depletion of doctors in consequence of the demands of the army. Innumerable doubts and difficulties have been settled for men seeking advice, and regulations based on recommendations of the Central Medical War Committee have been issued by the Army Medical Department.

Thus the efforts of the three committees have kept the army supplied with the medical officers required; but in order that there may be no falling off in the supply when further demands are made by the army, while at the same time keeping in view the needs of the civilian community, it has become essential that the whole profession should be organized so that every man may feel that he is doing his duty in connexion with the war. Hence the system of classification, grouping, and registration which was published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of December 11th, 1915, a system the development of which will form the larger part of the future work of the Central Medical War Committee.

From this historical summary it will be seen that the British Medical Association has not been behindhand in its efforts to do what lies in its power for the good of the country. It has placed its resources and organization unreservedly at the disposal of special committees on which all interests are represented. It has sunk its own identity, and endeavoured to give its utmost

support to national bodies fully representative of the whole profession. Its office has worked its hardest to make the work of the committees a success. Its JOURNAL, working in harmony with the *Lancet*, has done everything in its power to give publicity to the objects of the committees. The sacrifices made have already borne fruit. It rests with practitioners of all classes to see that the further work of the committees is even more successful, so that the medical profession may contribute to the fullest limit of its capacity to the attainment of victory.

Recently one of the great London daily papers has lent its columns to the publication of letters from critics of the present administration and organization of the Army Medical Service. Criticism is ever of the greatest value to those who are wise in the conduct of affairs; and there is ample evidence to show that both the Army Medical Department and the Central Medical War Committee have been duly receptive whenever valid argument has been advanced. The advocates of greater economy may be surprised to learn that within the last few weeks the use of some thousands of military hospital beds has been suspended; while retrenchment has been effected of some hundreds of medical officers in various capacities at the front. At the same time, the expansion of the army to some four million men will surely suggest to the least imaginative that further sacrifices are needed on the part of the medical profession no less than on the part of the lay community. As organization improves the need will become proportionately less great, but does any one suppose that an army of sixteen times its original strength can be built up in eighteen months without difficulties and without waste? Can any one point to any man or body of men whose hands and head are so free from occupation at the present time as to be able to produce perfect order in this enormous and hastily assembled machine? Are any of the critics, whose letters have been published broadcast, able to indicate with certainty the direction in which the economies they preach can be made immediately without loss of efficiency? A search through these letters reveals mountains of destructive criticism, but very little that is valuable for purposes of construction. Here and there a Government commission is hinted at; but does not history suggest that even this war may be over before such a commission makes its report? Do the writers of these letters suppose that the Medical War Committees have not gone deeply into the question of economy of medical officers from the fighting line to the base? Progress in reform must, of necessity, be slow; but all suggestions for improvement are welcomed, discussed, and, whenever they seem capable of adoption, urged in the proper quarter. It will be recognized that at the present time there must be an intermediary body between the civil practitioner and the Army Medical Department. Equally clear is it that there is no other body at all comparable to the Medical War Committees for dealing with the difficulties on both sides. Setting aside the demands of their own professional work, and being representative of all interests, while unfettered by lay control, the members of these committees have devoted much time to the problems that have come before them. Guided by the principle that this war must be speedily finished, and finished victoriously, the committees have endeavoured to set before the medical profession a lofty conception of duty. They aim at aiding the war authorities to appreciate civilian difficulties, to smooth the paths of those called upon to make sacrifices, to put to the best use the material

so freely offered. They endeavour to preserve to the civilian community as adequate a medical service as the military preparations against the gravest of perils allow. To all medical men they tender advice and assistance based on sympathetic understanding of the needs of the profession. If doubt is thrown upon the capacity of the three committees to carry out the work which they have set before them, the least that can be expected is that critics should offer alternative workable plans. Until such plans are forthcoming, capable of meeting the needs of the army no less than the medical requirements of the civil population, it would seem that the Medical War Committees are entitled to respect for honest and thoughtful work, and the British Medical Association to credit for the expenditure of its means and organization in furtherance of the requirements of the country.

MATERNITY AND CHILD WELFARE CENTRES.

Though the absorption of the nation in the prosecution of the war has necessarily diverted most of the energies of the Association towards the organization of the profession to meet the strain upon it, other matters of great importance have presented themselves for attention, of which we can only deal here with a few. The chief is undoubtedly the new movement by the Government and local authorities concerning maternity and child welfare schemes. To those who have given this matter serious attention it would appear that it may have a most vital influence on the future status of the general practitioner and on his relations with the public. Whether it is destined to lead to a further socialization of medical practice and a large development of medical officialism, or to a recognition on the part of the public that it would be a fatally short-sighted policy to weaken the position and undermine the usefulness of the general practitioner, is at present on the knees of the gods. But the decision is largely in the hands of the medical profession itself; the Representative Meeting of 1915 laid down the main lines of its policy, which is to utilize the opportunity for increasing the usefulness of the general practitioner to the community and thereby enhance his status. It is certain that in spite of preoccupation with the war this is a matter which demands constant watchfulness.

THE SELECT COMMITTEE ON PATENT MEDICINES.

Another matter of great interest was the consideration of the report of the Select Committee of the House of Commons on Patent Medicines. This report was a very significant and most satisfactory recognition of the principles for which the Association has contended for years, and was in effect a complete justification of the arduous campaign carried on for so many years in the columns of the JOURNAL, including the publication of a long series of articles embodying analyses of a large number of preparations. This material was afterwards collected into two books, *Secret Remedies* and *More Secret Remedies*,¹ which attained a very large circulation among the public. It was obvious to the Council that it is at the present time impossible for the Association to gather the fruits of its victory by pressing Parliament to put into the form of an enactment the recommendations of its Committee, but the opportunity was taken to secure from the Chairman of that Committee his promise that when the appropriate time came the report would be pressed on the attention of Parliament.

¹ *Secret Remedies: What they Cost and What they Contain*; and *More Secret Remedies: What they Cost and What they Contain*. London: British Medical Association, 429, Strand, W.C. (Price 1s. each; postage, 3d. each.)

LEGAL RESPONSIBILITY FOR CRIME.

The report of the Association on the present state of the law with regard to legal responsibility for crime, prepared in conjunction with the Medico-Legal Society, the Medico-Psychological Association, the Bar Council, and the Incorporated Law Society, has won much praise from those who understand how unsatisfactory the present law and practice in regard to this matter are, and in addition has, it is believed laid the foundation for future good work in medico-legal matters in co-operation with bodies whose interests in such matters are great, and whose influence is wide-reaching.

ASSISTANT ASYLUM MEDICAL OFFICERS.

A good example of co-operation with bodies representing sections of the profession which has for so long been the practice of the Association was the determination of a policy as regards the conditions of employment and remuneration of assistant asylum medical officers, reached in consultation with the Association of Assistant Asylum Medical Officers of England and Wales.

INSURANCE ACTS.

In the ordinary course of events the end of the year would have seen the revision of the terms under which medical practitioners are engaged in working the Insurance Acts, but this matter has perforce been postponed until a more favourable opportunity. The year has been characterized by a steadily increasing closeness of co-operation between the Association and those committees which specially represent panel practitioners. During the campaign which preceded the passing of the Act of 1911 the Association strongly emphasized the necessity of the establishment of such committees; since then its fixed policy has been to help them as much as possible by advice and such assistance as can best be given by a central organization. For the third year in succession a conference of representatives of Local Medical and Panel Committees was held, and that of 1915 was undoubtedly the most representative and business-like of all. The conference marked its sense of the usefulness of the Association to panel practitioners by definitely recognizing it as the central mouthpiece of the local committees in dealing with the Government and the Commissioners, and the latter body has recognized this relationship by consulting the Panel Committees on matters of general importance through the Insurance Acts Committee of the Association, which has now been strengthened by the addition of members nominated by the Conference to represent the Local Medical and Panel Committees of the country. Such a relationship augurs well for the future, for it must be clear to all that when the war is over matters of the greatest importance to the profession in general and to panel practitioners in particular will present themselves for consideration and decision; it will be well that when the occasion arises it should be found that so far as the great majority of the Panel Committees are concerned they are prepared to present their case through an experienced central body with the influence, organization, and financial backing of the British Medical Association. It is not necessary to attempt any more detailed examination of this branch of the Association's work, for the facts are well known to members, but a passing reference may be made to the recent success of the Association in claiming and securing what the great majority of Panel Committees demanded in connexion with the recent changes in the finance of the Drug Fund

brought about by the report of the Departmental Committee on the Drug Tariff—namely, an assurance from the Government that until a general revision of terms takes place the 7s. a head set aside for medical attendance on insured persons shall not be touched for the purpose of making up any deficiencies in the Drug Fund. This one result of the Association's work for 1915 in this department is a good augury for the success of its future efforts.

THE MIND OF A PROFESSION.

MR. COPE CORNFORD's little book about the navy—*With the Grand Fleet*—is valuable for two reasons: First, because it does not boast of numbers of ships or weight of armament, but describes the mind of the fleet. As Lord Charles Beresford says in his introduction: "The many generations of seamen, who strove through their lives to make the service what it ought to be, have created a body of thought, of tradition, and of aspiration, which is the inheritance of the navy of to-day, and which may be called the Greater Mind. . . . It is the Greater Mind in the navy which has gained the mastery of the sea." It is valuable, secondly, because by showing the mind at work it affords to the landsman an example of the absolute subordination of every action to the one idea of duty—duty to the nation, irrespective of what politicians at Westminster or officials at Whitehall may do or leave undone. There is no set of men in whom the professional spirit is so strong, and it pervades all ranks. The politicians come and go, and the tendency of permanent officials of all departments to mistake the means for the end, machinery for output, is so strong that few escape it. But the mind of the navy has gone on and grown. In the end the collective mind of the men who know, the men of thought and of action, wears away the obstructions put in its way by long-tailed officials, whose horizon is bounded by returns and memorandums, and minutes, and "what the country will stand," and the other shibboleths. "The Navy," again to quote Lord Charles Beresford, "desires nothing but to be left to do its own work in its own way, governed and guided by naval authority." It is a right for which every profession has to fight. The bar fought and won its battle long ago, and is to-day a remarkable piece of human organization very admirably adjusted to its purpose; it is the palladium of the liberty of the individual. The Navy, the palladium of our national liberty, has had to fight the dark powers of politics and officialdom generation after generation. In quiet times it has lost the right to do its own work in its own way, but the mind of the navy has lived on: you cannot strangle a mind even with red tape, or do more than hamper it by political foolishness, and in times of stress the navy has regained its right. The Church long ago sold its freedom for a mess of pottage, and the lovers of freedom at both extremes revolted. Medicine has only recently come into contact with the deadening influence of the official, and hardly yet realizes the narrowness of his outlook and the mischief he is capable of doing to the nation should he be allowed to prevail. Therefore, it is worth the while of every medical man and woman to read Mr. Cornford's book to see what peril the nation has escaped and how it escaped, and also for the lifting up of his or her soul at this season when the elements seem to conspire with the newspapers to enwrap us in an atmosphere of gloom.

MYELOID LEUKAEMIA AS AN INFECTIOUS DISEASE.

MYELOID LEUKAEMIA is a disease that appears spontaneously in barnyard fowls from time to time. Dr. H. C. Schmeisser¹ has recently come across a case, in a

Plymouth Rock hen, and has succeeded in transmitting the disease to other fowls and to chickens up to the fifth generation. The transmission was effected by the intravenous or intraperitoneal injection of fragments of liver or spleen, thoroughly macerated in normal saline solution and roughly filtered through cotton or linen, or through filter paper if the injection was given intravenously. Out of 105 animals used in the different experiments, 22 developed the leukaemia, and a similar diagnosis suggested itself in 4 more. The incubation period was usually five or six weeks, with a maximum of sixteen; the onset of the disease was sudden, with pallor and rapid emaciation, weakness, but no fever. The illness lasted a week or two; only one case recovered. The character of the blood count changed rapidly. Whereas the normal hen has 3 or 4 million red cells and from 20,000 to 80,000 white cells per cubic millimetre of blood, with from 60 to 70 per cent. of haemoglobin, as estimated by Sahli's instrument, the hen with myeloid leukaemia will have less than a million red cells and perhaps 200,000 white cells per cubic millimetre, and the haemoglobin may fall to 10 or 15 per cent. The differential leucocyte count also shows great changes. Normally, the hen may have 42 per cent. of lymphocytes, 34 per cent. of eosinophile polymorphonuclears, and 20 per cent. of large mononuclear cells of myeloid origin. In the form of leukaemia studied by Dr. Schmeisser the large mononuclear cells may form 86 per cent. of the leucocytes. The liver and spleen are both greatly or even enormously enlarged, being packed with aggregations of myeloid leucocytes; the kidneys are enlarged, and the bone marrow shows a characteristic loss of fat with increase of marrow cells. The blood picture and the *post-mortem* changes in the organs were the same in the original case as in those produced by the injection of tissue emulsions into healthy fowls. Dr. Schmeisser notes that infectious leukaemia in fowls was first properly recognized by Butterfield in 1905, and that the disease was first transmitted to other healthy fowls by Ellerman and Bang in 1908; Ellerman recently found that the infection could be conveyed by Berkeley filtrates, and observed that the transmitted leukaemia might be of either the myeloid or the lymphatic type. Dr. Schmeisser has not yet published his study of the nature of the infecting agent in his case of spontaneous myeloid leukaemia in the fowl. It should prove to be of great interest, for the reason that the disease as it occurs in these animals has obvious analogies with the lymphatic and myeloid leukaemias in man; here the disorder has all the appearances of an acute or subacute infectious process, yet its infectivity is unproved, and the virus producing it is at present wholly unknown.

A PLEA FOR THE SICK SOLDIER.

WHILE in these days the wounded soldier is much in evidence, and is naturally and rightly an object of sympathetic interest to us all, there is perhaps some danger that the man who has been invalided on account of sickness may be a little neglected. But while he makes less appeal to sentiment, his suffering is not less real, while his incapacity may be worse than that of his wounded brother in arms. M. Bachimont, deputy for the Aube, proposed in his interest to amend a bill as to the award of decorations for war service in which the military medal was reserved for wounded men. In support of this Professor Landouzy, Dean of the Paris Faculty of Medicine, addressed a letter to M. Bachimont, in which he asked with pardonable warmth whether the sick—on whom typhoid, diphtheria, scarlatina, dysentery, cerebro-spinal meningitis, or tuberculosis had left their mark in permanent damage of the nervous system, the heart, the liver, or the kidneys—were not as deserving of respect and pity as if they had lost an arm, a leg, or an eye by shell fire. A man disabled by functional trouble of an

¹ *Journ. Exp. Med.*, vol. xxii, p. 820.

internal organ is often left in a worse state than one who has lost a limb. Soldiers invalided out of the service on account of sickness have before them, M. Landouzy pointed out, the prospect of dragging out a precarious, difficult, and painful existence; and to those who have a keen sense of the duty they owe to society life may be further darkened by the knowledge that if they marry with constitutions undermined at an early age, they are likely to beget feeble and unsatisfactory offspring. M. Landouzy, while pleading the cause of the man disabled by sickness, makes him the text for a vindication of the place of the physician in war. In their inmost hearts, he says, people in general think they owe a greater debt of gratitude to surgery than to medicine; he, on the other hand, maintains that medicine, which has now at its disposal in vaccines and serums powerful means of preventing and curing the infections that threaten soldiers, is as beneficial as the conservative surgery of mutilated limbs. Even now it is not fully realized that until the other day armies in the field paid a heavier tribute to disease than to wounds. In proof of this M. Landouzy points to the fact that of the 100,000 Frenchmen who died in the Crimea 80,000 fell victims to typhoid, typhus, dysentery, cholera, scurvy, and other diseases.

NOTIFICATION OF MEASLES.

THE general order of the Local Government Board for the compulsory notification of measles and German measles comes into force on January 1st, 1916, throughout England and Wales. The order is addressed, among others, to medical practitioners. Every medical practitioner is required, so soon as he becomes aware that a person upon whom he is in professional attendance is suffering from measles or German measles, forthwith to make a notification on the proper form and send it to the M.O.H., unless he has reasonable ground for supposing that it has already been notified, or unless a case of the disease has to his knowledge occurred in the same household or institution, and has been notified within the period of two months immediately preceding the date on which he first became aware of the disease. If, however, the case is being treated in a hospital for infectious diseases, the practitioner is not required to notify it. There is every reason to suppose that about 55 per cent. of the cases of measles occurring are never seen by a doctor; some help in overcoming the difficulty thus created has been given by school notifications, but the majority of cases occur at the age of 4 years or under, and it is at these ages that the largest number of deaths are recorded. The Order also requires every parent or guardian, or other person, who becomes aware of or who has reasonable grounds for supposing that any person in his charge is suffering from measles or German measles to notify the M.O.H., unless he knows it has already been notified by a medical practitioner. The Order further authorizes all public health authorities throughout the country to provide nursing assistance for necessitous cases of measles. Hitherto a special order from the Board has been necessary to give a local authority this power. It may now provide or contract for the provision of medical and nursing assistance for the poorer inhabitants of the district when suffering from either measles or German measles, and instruct the M.O.H. to take steps to investigate the source of infection, to prevent its spread, to remove conditions favourable to it, and, if a medical practitioner is not in attendance, to ascertain the nature of the case. It is believed that the symptoms of measles are sufficiently pronounced and well known to enable the parent or the health visitor to entertain at least a suspicion of the nature of the disorder, but this is, of course, a weak point in the scheme. The power given to all sanitary authorities to provide nursing assistance under the Order is most important. It is the first instance, apart from tuberculosis, in which this power has been given generally to sanitary authorities. There is reason to hope that by its

judicious use a large saving of life will be effected by diminishing the toll of deaths now due to measles among impoverished children under school age

MEDICAL HERALDRY.

PROBABLY the great majority of medical men would, if called upon for a declaration of faith on the subject, have to make the confession with which Francis Osbaldistone shocked Di Vernon when he said, "The mysteries couched under the grim hieroglyphics of heraldry are to me as unintelligible as those of the pyramids of Egypt." Yet medicine has a heraldry of its own, and much ingenuity has been shown in devising armorial bearings for doctors whom the King for good and sufficient reason delights to honour. In an interesting article published in the November and December numbers of the *Antiquary* Dr. S. D. Clippingdale gives the fruits of a laborious research in this obscure field of historical lore. He describes, in many cases with illustrations, the coats of arms granted to medical corporations and to individual members of the profession. He says that probably the first medical man in this country to receive a grant of arms was John Leche, surgeon to Edward III, who was thus honoured because he had taken upon himself the costly duty of entertaining in his house at one time three sovereigns—the Kings of England, Scotland, and France. This would seem to suggest that in the fourteenth century surgery was a very lucrative profession. In devising arms for doctors the heralds have sought inspiration from traditional symbolism, from what may be called the weapons of the craft, and from the personal achievements of the individual honoured. In the first of these categories are the rough staff of Aesculapius with the serpent entwined about it, and the Mercury's wand or caduceus, a slender metal rod with two serpents coiled round it, and two expanded wings attached to the upper end. The appropriateness of the staff of Aesculapius is of course obvious; it figures in the arms of Sir Henry Halford, Sir Joseph Fayrer, Lord Lister, Sir James Young Simpson, Sir William Savory, Sir Henry Thompson, and Sir Thomas Barlow, and it forms the badge of the Royal Army Medical Corps. Serpents have a place in the arms of Sir Samuel Wilks, Sir Gilbert Blane, Sir William Gull, Sir Prescott Hewett, Sir William Jenner, Sir Trevor Lawrence, and Sir Thomas Crosby, late Lord Mayor of London. The earliest appearance of the caduceus in English medical heraldry is, according to Dr. Clippingdale, on the crest of Sir William Butts, physician to Henry VIII. Modern instances are seen in the arms of Sir William Broadbent, Sir George Burrows, Sir Lauder Brunton, Sir Rickman Godlee, and Lord Ilkerton. The precise meaning of the caduceus as a symbol of the art of healing is not apparent. Mercury was in the old Roman mythology the patron of tradesmen and thieves, but we cannot admit that in this character he can be regarded as having any connexion with medicine. Mercury was also venerated as the messenger of the gods, a function expressed by the wings in the caduceus; in this capacity he may perhaps be accepted as symbolical of medicine. Lamps and other means of illumination, denoting the light of science, figure in medical heraldry. Flaming torches are seen in the arms of Sir John Williams, Sir James Reid, Sir Henry Thompson, and Sir Thomas Barlow. The lamp has a place in the arms of Sir William Jenner and Sir William MacCormac. The eagle, which occurs as the crest of the Royal Colleges of Surgeons of England and Edinburgh, is also found in the arms of many medical men. The anchor, emblem of hope, is of frequent occurrence. Of the weapons of the craft, the most common, as it is the earliest, is the fleam or lancet, which is found in the coat of arms granted to the Surgeons' Company of London in 1451; supported by the Ophiuchus, a fabulous animal credited with healing powers, it forms the crest of Sir Frederick Treves. The spatula is seen in the arms of the

Barber-Surgeons' Company, and knives, saws, forceps, and other instruments form the border of those of the Edinburgh College of Surgeons. Among the medicinal plants which figure in heraldry may be mentioned the pomegranate in the arms of the Royal College of Physicians, and digitalis in those of Lord Ilkeston. In this case the plant was chosen as symbolizing the work on the heart, on which the reputation of the physician who in his practising days was known as Balthazar Foster was mainly founded. Other plant emblems are the iris flower in Sir Anderson Critchett's crest, which is probably an allusion to that eminent surgeon's operations on the eye; and the daisies in Sir Richard Quain's arms, which, according to Dr. Clippingdale, are understood to have been inserted because that was his favourite flower.

CASUALTIES AND RECOVERIES.

IN a short note in our last issue on some statistics circulated in Germany as to the number of wounded who, during the first year of the war, had died, had been discharged as unfit, or had been returned to duty, it was pointed out that the figures conveyed no information on the point of real importance, namely, the percentage of men wounded in the firing line who recovered so completely as to be able to return to it. The object with which such figures were circulated was no doubt mainly to convey the impression that the percentage reported to be discharged from hospital were effectives who returned to the firing line, and in this way to encourage the German people and throw dust in the eyes of neutral countries by discrediting the calculations as to the wastage of the German armies. It was also, no doubt, intended to glorify German surgical methods as compared with those of the surgeons of the allied nations, for it was boasted that the armies of no other nation could show like favourable results. As a matter of fact, the comparable statistics of the British army are rather better, and though the French figures given on the authority of M. J. Bertillon, the well-known medical statistician, were not quite so good, it is not clear that they are comparable, as they appear to include all wounded men who reached a hospital in France, whereas the German and British referred only to men who reached a hospital in Germany or the United Kingdom. We said then that the figures given were fallacious so far as they purported to indicate the amount of wastage; and it is interesting to find this view more than confirmed in a recent article by the Swiss military writer, Colonel Feyler. The article is in the main a warning to the Allies not to let themselves be misled into supposing that Germany has yet reached the end of its man power, although he thinks this point may be reached next spring. He says, however, that in a particular army corps for which statistics were available to him, the proportion of the men who have remained at the front since the beginning of the war represent 12 per cent. of the effectives sent there at the beginning, and that a somewhat large proportion—about 20 per cent.—are men who, after being evacuated, have recovered and returned to the front after an average interval of four months. In this corps, therefore, 68 per cent. of the men who belonged to it at the beginning of the war have been replaced. According to the figures given in the House of Commons by Mr. Tennant on December 21st, the total casualties of the German army as published in the official casualty lists for Prussia, Saxony, Bavaria, and Wurtemberg down to November 30th, 1915, numbered over 2 millions and a half. About half of these were accounted for under the heads of killed or died of wounds (nearly half a million), severely wounded, died of disease, or missing. This leaves about a million and a quarter casualties unaccounted for, and it is on the proportion of wounded among them that any calculation as to the number of men who return to the fighting line can alone be founded.

According to the statistics given in a written answer by the Prime Minister on December 23rd, the total casualties in the British force in Flanders and France, the Dardanelles, and other theatres of war, amounted to rather over half a million, of whom nearly 120,000 were killed. These figures do not include the sick, of whom there were nearly 100,000 admitted to hospital from the Dardanelles operations alone between April 25th and December 11th. The proportion of missing, which no doubt includes a majority of killed, is about one-seventh in the armies of both countries, but is a fraction higher in the British than in the German.

MEDICAL ENROLMENT.

THE decision to adopt the principle of compulsory military service need not affect the position of members of the medical profession, inasmuch as the arrangements made in advance by the Medical War Committees will, there is every reason to expect, suffice to meet all the demands of the medical service of the army. The history of these committees is given above (p. 20 et seq.), and the general character of the scheme worked out is there very fully set forth. Full details of the plan of the Scottish Medical Service Emergency Committee are given in the SUPPLEMENT this week (p. 1), and the details of the method of procedure in England and Wales, which it is hoped to announce finally next week, will, no doubt, be on the same lines as have been arranged in Scotland. Medical men in England and Wales who have not yet enrolled should at once do so through the Medical War Committee for the area in which they reside. All these local committees are in direct communication with the Central Medical War Committee for England and Wales, which will give to each applicant a certificate of enrolment. It has made arrangements for the grouping of members of the profession in the manner stated in its circular letter to the local Medical War Committees published in the SUPPLEMENT of December 11th, 1915, p. 214. With regard to the order in which individuals should be called on for service, the Central Medical War Committee will consider, in co-operation with the local Medical War Committees, the special difficulties of any individual practitioner, with a view to meeting them, or, if necessary, relegating him to a later group. The present position, therefore, is that medical men should not attest under Lord Derby's schemes, but should enrol with one of the national Medical War Committees. On any point of personal difficulty medical men in England and Wales are invited to communicate direct with the secretaries of the Central Medical War Committee, 429, Strand, London, W.C.

THE Leeuwenhoek medal of the Netherlands Academy of Sciences, awarded to Surgeon-General Sir David Bruce, F.R.S., A.M.S., was presented to him on December 24th by the Netherlands Minister in this country. Leeuwenhoek was a Fellow of the Royal Society, and the majority of his discoveries were published in the *Philosophical Transactions*. The medal was founded in 1875, on the occasion of the Leeuwenhoek celebration in Delft, and is presented every ten years. It was awarded to Ehrenberg in 1875, to Ferdinand Cohn in 1885, to Louis Pasteur in 1895, and to Beyerinck in 1905.

A MEMORIAL of Eustachius was recently unveiled in the great quadrangle of the University of Rome in the presence of the Prime Minister, the Minister of Public Instruction, the Mayor of Rome, and the rector and members of the Senate of the University. The memorial, which is a bronze tablet attached to one of the pillars of the upper portico, near a marble memorial of Victor Emanuel II, represents Eustachius in his professor's robes in the act of lecturing; he holds in his left hand a human skull and the right arm rests on tables showing the structure of the ear. The inscription by Professor Giacomo Gori is as follows: *Bartholomaeo Eustachio, Picenti, Artis anatomicae lumini, Senatus Academicus, quartis feris secularibus, Anno MDCCCXIV.*

Medical Notes in Parliament.

War.

Total Casualties.—In a written reply to Mr. Molteno, on December 23rd, the Prime Minister supplied the following statistics of the total casualties in all fields of operations down to December 9th, 1915:

Flanders and France.

	Officers.	Other Ranks.
Killed...	4,829	77,473
Wounded ...	9,943	241,359
Missing ...	1,699	52,685
Total ...	16,471	371,517

387,988

Dardanelles.

Killed...	1,667	24,535
Wounded ...	3,028	72,781
Missing ...	350	12,194
Total ...	5,045	109,510

114,555

Other Theatres.

Killed...	871	10,548

25,684

Grand Total All Theatres.

Killed...	119,923
Wounded ...	338,758
Missing ...	69,546

528,227

Mediterranean Casualties.—In reply to Mr. Joynson-Hicks, Mr. Tennant stated on December 23rd, 1915, that the total casualties in the Dardanelles to December 11th, 1915, including the Naval Division, were:

	Officers.	Other Ranks.
Killed (including died from wounds and died) ...	1,609	23,670
Wounded ...	2,969	72,222
Missing ...	337	12,114
Totals ...	4,915	108,006

Grand total ... 112,921

Sick admitted to hospital April 25th to December 11th, 1915 ... 96,683

In reply to a further question, Mr. Tennant said that there was every reason to hope that sickness would be a decreasing quantity. In regard to the time allowed before men returned as missing could be counted as killed, it was necessary to allow a long time, but in many cases unofficial reports came from comrades, and in such cases from four to five months would be about the time taken to give a certificate of death. In regard to the returns of casualties from France, those invalided home sick were not included among the wounded.

German Army Casualties.—Mr. Tennant stated, on December 21st, in reply to the Earl of Kerry, that the total casualties as published in the official casualty lists for Prussia, Saxony, Bavaria, and Wurtemberg up to November 30th, 1915, amounted to 2,524,460. Of these there were, according to the official lists:

484,218 killed and died of wounds.
384,198 severely wounded.
27,674 died of disease.
381,149 missing.

Men Discharged as Medically Unfit.—On December 23rd Mr. Tennant informed Sir E. Cornwall that statistics of the number of enlisted men discharged from the army as medically unfit after less than six months' training were not available, and could not be compiled without throwing an undue strain on an already overworked department.

Hospitals for Officers.—On December 23rd Mr. Newdegate asked whether the grants allowed to hospitals for officers, which received no other form of assistance, were varied in amount; what was the maximum and minimum grant; and why there was inequality. The Financial Secretary to the War Office said that many sick and wounded officers received care and treatment in private hospitals provided by the praiseworthy generosity of

people of sympathy and wealth. Other officers were on occasion accommodated in nursing homes. Where payment or assistance from public funds was asked for, each case was considered on its merits.

Pensions and Grants.—The Financial Secretary to the War Office undertook, on December 23rd, to inquire into any cases in which there was reason to suppose that right had not been done with regard to grants to dependent soldiers in accordance with the recommendations of the Select Committee.

Leprous German Prisoner.—In reply to Mr. Butler Lloyd, Mr. Tennant said that a German prisoner of war suffering from leprosy, who had been for some months within a few paces of the sentry and guardroom at Handsforth, near Manchester, was being removed to a hospital at Dartford, where special accommodation had been prepared for him. He did not think it would be well to send this prisoner back to his own country with the next party of exchange prisoners.

Medical Units in Serbia.—In reply to Mr. Mills, Sir Edward Grey said, on December 22nd, that no list of the doctors and nurses who have left Serbia had been received; the latest information was that Sir Ralph Paget arrived at Brindisi on December 18th with 120 members of the medical missions to Serbia.

Female Nurses in Asylums.—In reply to Mr. Jowett, who asked whether steps would be taken to prevent any further appointments by asylum committees of female nurses in place of male attendants, the Home Secretary said that the Board of Control was watching the matter carefully. The employment of female nurses to release men for enlistment was allowed in suitable cases and under proper safeguards.

Vaccination Prosecutions in Dublin.—In reply to Mr. Nugent, on December 22nd, Mr. Birrell said that legal proceedings had recently been instituted in Dublin against defaulters under the Vaccination Acts. The papers did not show whether the persons in default were civilians or whether any of them belonged to the army. There were no exemptions from vaccination, and it would be most unfair if children were not protected from the danger of small-pox while their fathers were at the war.

Chlorine Gas for Living Animals.

The following appears in the *Official Report of Parliamentary Debates in the House of Commons*, December 21st, 1915:

Mr. Greenwood asked the Home Secretary whether he has granted a certificate under the Cruelty to Animals Act, 1876, to Mr. Leonard Hill, under which Mr. Hill performed a number of experiments upon living animals with chlorine gas, as reported in the *BRITISH MEDICAL JOURNAL* of December 4th, 1915; if such experiments were performed in the United Kingdom, where were they performed, what were the terms of such certificate, and who was the person who signed the same as required by the said Act; what were the animals used by Mr. Leonard Hill in these experiments, and how many of such animals were so used; and, if more than one kind of animal was used, how many of each kind.

Sir John Simon: I have made inquiry, and find that the research described in the article referred to was conducted jointly by Dr. Hill and Dr. Flack, but that all the experiments referred to were performed by Dr. Flack. They were performed in the laboratory of the Medical Research Committee at the London Hospital Medical College, and six were done under licence alone and twelve under Certificate A. Under licence alone six animals were used (five cats and one rabbit), and under Certificate A twelve guinea-pigs. Dr. Flack's certificate A was given by the President of the Royal Society and the Professor of Physiology, London University.

At a meeting held recently at New York it was stated that the America Red Cross aims at getting an endowment fund of £20,000, and a membership comprising every man, woman, and child in the United States. The wish was also expressed that all the American war relief societies should be amalgamated in its organization. Ex-President William H. Taft, recently appointed Chairman of the Central Committee of the Red Cross, was among the speakers.

RESULTS OF ANTITYPHOID VACCINATION IN THE FRENCH ARMY.

DR. JULES COURMONT, who is in charge of the isolation hospitals of the XIV District (French military administration), has issued an interesting report on the results of antityphoid vaccination from August 2nd, 1914, to July 1st, 1915. Haemoculture was employed for diagnostic purposes wherever possible, as it was recognized to be the only really trustworthy guide to the nature of the infection. The cases observed, in fact, included a large proportion of infections by paratyphoid organisms.

The total number of admissions of patients diagnosed to be suffering from typhoid fever was 1,347; of this number 891 had not been vaccinated, and 256 had been inoculated from one to four times with Vincent's non-polyvalent vaccine; of the 891 unvaccinated, 506 came from the front and 385 from the XIV District; of the 256 vaccinated, 96 came from the front and 160 from the XIV District.

The number of deaths among the 891 unvaccinated was 155 (17.4 per cent.); of these, 80 were from the front and 75 from the district. There were only 8 deaths among the 256 vaccinated (6 from the front and 2 from the district). If the subjects who received the regulation four inoculations were accepted as vaccinated the percentage of deaths would only be 1.9. The following is the complete table:

Admissions.	Total.	Front.	XIV District.	Slight Fever.	Medium Fever.	Grave Fever.	Deaths
1 injection ...	51	19	32	35	12	4	3
2 injections ...	■	■	25	36	10	4	■
3 injections ...	39	20	19	24	13	2	1
4 injections ...	116	32	84	■	77	2	2
Total ...	256	96	160	■	64	11	8

This gives:

	Non-vaccinated	Vaccinated:	Deaths.
1 injection	17.4 per cent.
2 injections	6.0 per cent.
3 injections	4.0 "
4 injections	2.5 "
			1.9 "

From the bacteriological point of view the proportion of paratyphoids was high. Haemoculture was used in 100 cases of the vaccinated, and proved negative in 25 and positive in 75. Of the 75 positive cases, 3 yielded Eberth's bacillus (2 of these had only had a single injection, and of these 1 died, the third had 2 injections); 71 yielded paratyphoid B and 1 paratyphoid A. Of the 116 infected patients who had received the four injections 63 showed paratyphoid B.

Antityphoid vaccination is thus shown to be unquestionably active and efficacious, but these figures point to the desirability of making use of a polyvalent vaccine (Eberth, paratyphoid A and B).

PUBLICATION OF SCIENTIFIC PAPERS.

(From a Correspondent in Northern France).

A FEW weeks ago there was circulated for general information a memorandum by the D.G.M.S. in regard to articles submitted for publication in professional journals. To this it is worth while to direct specific attention since its purport has in many quarters been misunderstood. The memorandum ran as follows:

The following resolution was passed at a meeting of R.A.M.C. Library and Journal Committee held in London on October 22nd, 1915:

"That it be represented to all officers of the R.A.M.C. and to those holding temporary commissions in the R.A.M.C. both at home and overseas, that the *Journal of the R.A.M.C.* should be considered the first in which military medical articles of permanent interest should be published.

"Articles intended for publication in journals such as the *BRITISH MEDICAL JOURNAL* and *Lancet* should at the same time be offered to the *Journal of the R.A.M.C.*

"The Director-General, British Army in the Field, and the Principal Director of Medical Services Mediterranean Force, to be informed accordingly."

All administrative medical officers and officers in command of medical units are requested to encourage officers to send in articles in accordance with the terms of this resolution.

This circular, though not obscurely worded, was interpreted by some as an intimation that medical officers serving with the Royal Army Medical Corps and desirous of recording their views or experiences in professional connexions must give their preference to the *Journal of the Royal Army Medical Corps* itself, and that unless they did so permission to publish their articles at all was not likely to be forthcoming.

I am in a position to state that any such view is not only erroneous in itself but is quite opposed to the aims of the medical authorities out here. They desire not only to encourage medical officers to study their cases carefully, but also to assist them as far as possible in interchanging any views they may form. Obviously such interchange of views would be handicapped if medical officers had to limit their search for publication of any articles they may write to one particular journal, and more particularly if such journal were one which appeared only at monthly intervals.

The object of the medical authorities in France in affording publicity to the resolution of the R.A.M.C. Library and Journal Committee which has been quoted was decidedly not to suggest that the authors of articles should aim at publication in that *Journal* alone. It was to bring home to them the existence of that *Journal*, and to show them that if they pleased they could have a chance of securing publication in two medical periodicals instead of one alone. Between a monthly journal and a weekly journal there is never any rivalry, and the fact that an article is submitted simultaneously to two publications of this order is not likely to lessen the probability of its acceptance by either of them.

Consequently, all that medical officers have to do to secure the chance of double publication is to mark one of the two copies that they must in every case submit as being intended for the consideration of the weekly journal of their choice, and the other as for the consideration of the editor of the *Journal of the Royal Army Medical Corps*.

Two copies of any article for which it is desired to secure publication must be submitted in order to comply with the terms of paragraph 453 of the King's Regulations. As these Regulations constitute the common law of the British Army, whether in times of peace or of war, precise compliance with them is essential on the part of all ranks. As the wording of the Regulation in question does not seem to be well known, it is worth while to quote it here at full length:

An officer or soldier is forbidden to publish in any form whatever, or communicate, either directly or indirectly to the press, any military information or his views on any military subject, without special authority; and an officer or soldier will be held responsible for all statements contained in communications to his friends which may subsequently be published in the press or otherwise. He is not to prejudice questions which are under the consideration of superior military authority by the publication, anonymously or otherwise, of his opinions, and he is not to take part, in public, in a discussion relating to orders, regulations, or instructions issued by his superiors.

Any information of a professional nature which he may acquire while travelling or employed on duty is to be regarded as the property of the War Department, and is not to be published in any form without the previous sanction of the Army Council, or in India of the Commander-in-Chief.

When application is made for permission to publish any article, etc., the document will be either typewritten or in proof form, and will be submitted in duplicate direct to the War Office (or in India to the Commander-in-Chief). A statement will be enclosed from the authority (if any) under whom the applicant is immediately serving that such authority has no objection to permission being applied for. One of the copies will be retained at the War Office or by the Commander-in-Chief in India, as the case may be, for reference. Permission to publish will apply only to the article, etc., as submitted, and no alterations therein, except of a purely editorial nature, and no additions thereto are to be made subsequently without the authority of the Army Council (or in India of the Commander-in-Chief). The permission to publish the article, etc., will not convey any official endorsement of its contents, and no statement tending to imply official approval or endorsement is to be included in any part of the publication, nor is the permission to be referred to in any way.

It may possibly occur to some that as this regulation states that one copy must be retained at the War Office, authors who desire to see their papers published in two

journals ought really to submit three copies. This, however, is not really essential, for the *Journal of the Royal Army Medical Corps* is a semi-official publication, and all papers submitted for the consideration to its editor are handed in to the War Office itself. Consequently they can be duly filed thereat when their fate as to publication has been determined. The only object, of course, in insisting that two copies of any proposed paper should be submitted is to place a check upon any disposition on the part of an author to make other than purely verbal alterations in an article after it has been duly approved.

This approval or censoring is done at head quarters, and unless the contents of the article happen to demand the consideration of more than one department of the Commander-in-Chief's staff, they usually reach home within a few days of their receipt. They arrive, or rather should arrive, at head quarters after passing through the hands of the administrative officers to whom the medical officer concerned is directly subordinate—namely, the O.C. of his unit, the A.D.M.S. of the area or division in which he is serving, and the D.M.S. of the lines of communication or of the army to which the division in question is attached, as the case may be.

The following is a draft of the kind of letter that medical officers should send with their proposed articles:

From Captain John Smith, R.A.M.C.,
To O.C., No. 120 Casualty Clearing Station.

France,
Dec. 19th, 1915.

Sir,

I have the honour to submit herewith in duplicate an article on enteric. If approved, I request that one of the copies may be sent to the Editor of the *BRITISH MEDICAL JOURNAL* and the other to the Editor of the *Journal of the Royal Army Medical Corps* with a view to publication. They are marked accordingly.

I have the honour to be, Sir,

Your obedient Servant,

(Sd.) JOHN SMITH,
Captain R.A.M.C.

In conclusion, it is of interest to be able to record that since the first day of the current year (1915) up to the date on which I am writing—December 19th—the total number of articles submitted to head quarters by medical officers for publication is 141, and with one exception all have been approved and forwarded after verbal alteration, such as the erasure of the names of units the publication of which is, on military grounds, prohibited. How many of them have reached the light of day by appearing in the medical journals it is impossible to ascertain, but making due allowance for such as have been stillborn, owing either to lack of space or other purely editorial cause, the total output can hardly be deemed satisfactory in point of bulk, considering the vast amount of material that medical officers have had at their disposition.

HONOURS.

THE *London Gazette* of December 23rd, 1915, announces the grant of a number of honours, including two V.C.'s, six D.S.O.'s, and thirteen Military Crosses. One of the V.C.'s was an officer of the 25th, or Frontiersmen, Battalion of the Royal Fusiliers, killed in East Africa; four of the new D.S.O.'s were Canadians; while the Military Crosses included one Canadian and one officer of the Newfoundland Contingent. Two of the Military Crosses were conferred upon temporary officers of the R.A.M.C., Captains H. J. Burke and B. J. Hackett, for the following services. Captain Burke's name has twice appeared in the casualty lists as wounded.

Military Cross.

Temporary Captain Henry James Burke, R.A.M.C. (attached 1st 8th Battalion West Yorkshire Regiment, T.F.). For conspicuous gallantry on November 8th, 1915, near Turco Farm. A sergeant in the front line had his leg crushed by the blowing in of a dug-out, and Captain Burke found immediate amputation necessary. In order to save time he called across the open to get his instruments, while the enemy turned a machine-gun on to him. In spite of their fire he returned the same way and coolly performed the operation in the trench while the enemy were shelling it heavily.

Temporary Captain Bartholomew James Hackett, M.B., R.A.M.C. (attached 7th Battalion Suffolk Regiment). For conspicuous gallantry and devotion to duty at Loos on October 2nd, 1915. When the battalion to which he was attached had suffered very heavy casualties and had run out

of dressings, Captain Hackett brought up a fresh supply from the dressing station, crossing over about 1,000 yards in the open. He has frequently attended the wounded under fire, and has shown great bravery.

The Military Cross has also been conferred on Second Lieutenant (temporary) Thomas William Gerald Johnston, 5th Connaught Rangers, then a medical student of Trinity College, Dublin, in his fifth year. The award was made, as stated in the official dispatch, for conspicuous gallantry in Gallipoli on several occasions, notably on August 8th, 1915, during the attack on Lone Pine, when he showed the greatest personal bravery; and on August 21st, during the attack on the well and trenches at Kabak Kuyu, when he led his men in the most daring manner, and, entering the Turkish trenches, bayoneted seven Turks with his own hands. Mr. Johnston came home wounded, and completed his final medical examinations in December, 1915.

CASUALTIES IN THE MEDICAL SERVICES

Killed in Action.

COLONEL ERNEST OCTAVIUS WIGHT, R.A.M.C., was killed by a shell while helping to extricate some motor ambulances from a dangerous position near Ypres on December 19th, 1915. He was born in May, 1858, educated at St. Mary's Hospital, London, and in 1881 took the diplomas of L.R.C.P. Edin. and M.R.C.S.; he took the D.P.H. of the London colleges in 1902. He entered the R.A.M.C., then the Army Medical Department, as surgeon on February 6th, 1882, became surgeon-major on February 6th, 1894, and lieutenant-colonel on February 6th, 1902. He retired on March 6th, 1907, but when the war began he rejoined the army, and in April, 1915, was gazetted to be an Assistant Director of Medical Services, holding that post in the 49th Division when he was killed. He had previously seen service on the north-east frontier of India, in the Lushai campaign of 1892, and received the frontier medal with a clasp. He also held the Royal Humane Society's bronze medal and two vellum testimonials for saving life from drowning on three different occasions. Colonel Wight was the youngest son of the late Robert Wight, F.R.S., of the Madras Medical Service, and of Grazeley Court, Reading, one of the most celebrated botanists of his day.

Wounded.

Captain C. A. Bernard, R.A.M.C. (temporary), France.
Captain J. S. Hall, R.A.M.C. (temporary), Flanders.
Captain A. L. Shearwood, R.A.M.C. (Special Reserve), Mediterranean.
Lieutenant J. Campbell, R.A.M.C. (temporary), Mediterranean.
Lieutenant A. C. Edwards, R.A.M.C. (temporary), Flanders.
Lieutenant F. G. Foster, R.A.M.C. (Special Reserve), Flanders.

DEATHS AMONG SONS OF MEDICAL MEN.

Bath, J. E. W., Lieutenant 5th Battalion Royal Berkshire Regiment, eldest son of Dr. S. Bath, of Newfield, Marlow, killed in France on December 22nd. He was educated at Shrewsbury and at All Souls College, Oxford, and represented Oxford in the inter-university cross-country race in 1915. He joined his regiment as Second Lieutenant on August 29th, 1914.

Hyde, A. C., Major 1st Battalion Oxford and Buckinghamshire Light Infantry, son of the late Lieutenant-Colonel Hyde, I.M.S.

Macdonald, Colin, Captain 1st Attached 2nd Battalion 7th Gurkha Rifles, son of the late Dr. Macdonald, of Dumfries. He was born on May 6th, 1883, entered the army as Second Lieutenant on August 27th, 1902, joined the Indian army on December 18th, 1903, and became Captain on August 27th, 1911.

Stokoe, J. C., Second Lieutenant 12th Battalion Manchester Regiment, attached 6th Battalion Loyal North Lancashire Regiment, eldest son of the late Mr. J. C. Stokoe, M.R.C.S., of Newry. He joined as a Second Lieutenant on March 25th, 1915.

Ward, Charles Francis, Captain Royal Field Artillery, son of Charles Ward, F.R.C.S.I., District Surgeon, of Pietermaritzburg, Natal, killed near Ypres, May 15th, 1915. He was born on January 20th, 1884, joined the army as Second Lieutenant on December 23rd, 1903, became Lieutenant on December 23rd, 1906, and Captain on October 30th, 1914.

MEDICAL STUDENT.

Macrosty, Henry Hugh, Lieutenant Royal Field Artillery, only son of Mr. H. W. Macrosty, of the Board of Trade, killed in France on December 19th, 1915, aged 21. He was educated at Blackheath and at Edinburgh University, where he had completed his second year of medical study. He got his first commission on September 12th, 1914, went to the front in May, and was promoted to Lieutenant in September.

NOTES.

CARE AND EDUCATION OF CRIPPLED SOLDIERS.

In Italy doctors and philanthropists are showing great activity in providing aid for soldiers mutilated in the war. Provincial and local committees are being formed all over the country; these are grouped under a central "National Federation," having its head quarters in Rome. The Government has made large contributions to the funds of the organization, and the Red Cross Society, together with the local authorities and citizens of the various districts, are liberal in help. Committees have been formed at Lucca, Leghorn, and elsewhere for the aid of soldiers mutilated in the war, and in particular for their training in new occupations. At Reggio Emilia a section for blinded soldiers has been established in connexion with the Garibaldi Institute for the Blind. A large factory has been established at Milan for the making of artificial limbs for mutilated men. It is organized on a non-commercial basis.

It appears from a notice published in the *Deutsche medizinische Wochenschrift* for September 16th, 1915, that the Medical Department of the German War Office has issued orders in connexion with the care of war cripples, to prevent overlapping and delays in providing them with the necessary crutches and artificial limbs. It is pointed out that the transfer of the totally unfit to military hospitals in their home districts is often delayed until artificial limbs have been provided. Not only is invaluable time lost in this manner, but when an artificial limb is provided just before the cripple is sent to a hospital in his own district, readjustments of the artificial limb in such a district are rendered difficult by the fact that the cripple is no longer within easy reach of the firm which has supplied the limb in the first place. For these reasons the heads of military hospitals and other officials connected with the medical service are instructed to transfer, whenever possible, soldiers who have lost a limb to military hospitals in their home districts before providing artificial limbs. The difficulties of transporting by train soldiers who have lost their legs must not, it is added, prevent the execution of this plan, which, it is hoped, will not delay the timely care and education of war cripples.

MEDICAL OFFICERS WANTED.

Field Ambulance.

The Officer Commanding a Field Ambulance, who has had ten months' experience at the front in France and Belgium, is fitting out a Territorial London Field Ambulance for service abroad, and has vacancies for five medical officers. Rates of pay, etc., higher than temporary commissions abroad. Gratuity after one year, £96 2s. Address, No. 999, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

22nd South Midland Mounted Brigade Field Ambulance.

Medical officers are urgently wanted for this Field Ambulance. Intending candidates must be willing to sign for foreign service, and should apply to Major A. G. Magrath, Officer Commanding, London Road, Kings Lynn.

Scotland.

THE MIDWIVES (SCOTLAND) ACT.

THE Midwives (Scotland) Act has received the Royal Assent and comes into force to-day (January 1st), although many of its provisions will not take effect until later. Steps will, however, be taken at once to form a Central Midwives Board for Scotland. The composition of the Board was given in full in the JOURNAL for December 4th, 1915, p. 833. Its constitution is briefly as follows: (a) Three persons, two of whom shall be certified midwives practising in Scotland, to be appointed by the Lord President of the Council when the number of midwives so qualified is sufficient; (b) one appointed by the county councils, one by the burghs, one by the Scottish branch of the Jubilee Institute for Nurses, and one by the Society of Medical Officers of Health for Scotland; (c) five be registered medical practitioners, two representing the universities, one the Royal Colleges, and two appointed by the Scottish Committee of the British Medical Association.

The provisions regarding the practice of midwives in Scotland are imposed in two instalments, the first on January 1st, 1917, and the second on January 1st, 1922. They are as follows:

1.—(1) From and after January 1st, 1917, any woman who, not being certified under this Act, shall take or use the name or title of midwife (either alone or in combination with any other word or words), or any name, title, addition, or description implying that she is certified under this Act, or is a person specially qualified to practise midwifery, or is recognized by law as a midwife, shall be liable on summary conviction to a fine not exceeding five pounds.

(2) From and after January 1st, 1922, no woman shall habitually and for gain attend women in childbirth otherwise than under the direction of a registered medical practitioner unless she be certified under this Act; any woman so acting

without being certified under this Act shall be liable on summary conviction to a fine not exceeding ten pounds, provided this section shall not apply to registered medical practitioners or to any one rendering assistance in a case of emergency.

(3) No woman shall be certified under this Act until she has complied with the rules and regulations to be laid down in pursuance of this Act.

(4) No woman certified under this Act shall employ an un-certified person as her substitute.

(5) The certificate under this Act shall not confer upon any woman any right or title to be registered under the Medical Acts or to assume any name, title, or designation implying that she is by law recognized as a medical practitioner, or that she is authorized to grant any medical certificate, or any certificate of death or of stillbirth, or to undertake the charge of cases of abnormality or disease in connexion with parturition, but nothing herein contained shall prevent a midwife granting such certificates as may be required by the rules of approved societies or insurance committees in connexion with maternity benefit under the National Insurance Acts.

For women at present engaged in practice as midwives the Act provides as follows:

Any woman who, within two years from the date of this Act coming into operation, claims to be certified under this Act, shall be so certified, provided she holds a certificate in midwifery from the Royal Maternity Hospital of Edinburgh, the Royal Maternity Hospital, Glasgow, the Maternity Hospital, Aberdeen, the Maternity Hospital, Dundee, the Obstetrical Society of London, the Royal College of Physicians of Ireland, the Coombe Lying-in Hospital, and Guinness's Dispensary, the Rotunda Hospital for the Relief of Poor Lying-in Women of Dublin, the National Maternity Hospital, Dublin, the Central Midwives Board for England, or such other certificate as may be approved by the Central Midwives Board for Scotland; or produces evidence satisfactory to the last-mentioned Board, that at the passing of this Act she had been for at least one year in bona fide practice as a midwife, and that she bears a good character.

The period of two years may be extended by the Central Midwives Board for Scotland in special cases where any woman is able to satisfy them that she had reasonable excuse for having failed to make her claim within the prescribed time.

TUBERCULOSIS MATTERS IN EDINBURGH.

The Chief Veterinary Inspector, Mr. A. Gifton, F.R.C.V.S., has reported to the Edinburgh town council that during October 22 carcasses and 38 portions of carcasses had been surrendered at the abattoirs on account of disease, injury, or decomposition; and that of these 7 carcasses and 34 portions of carcasses had been destroyed on account of tuberculosis. He also reported that 2 cows had been removed from city byres on account of tuberculosis of the udder, that one of them had been slaughtered at the abattoir, but that it was not known what became of the other. In answer to a question, Mr. Young (Chairman of the Public Health Committee) stated that diseased animals were allowed to go out of the city because no local authority had any power to seize a cow suffering from tuberculosis, but could only remove her from a city byre. The council directed that a report on the subject should be prepared for its consideration.

At the annual meeting of the Royal Victoria Hospital Tuberculosis Trust it was pointed out that unfortunately the outbreak of the war had coincided with the rearrangement of the Royal Victoria Hospital scheme, and the committee had not felt justified in embarking on large outlays for the present. Sir Robert Philip mentioned the interesting fact that 24 of the former tuberculosis patients at the Royal Victoria Hospital were serving with the colours; one of them had been badly "gassed," but in spite of his former lung trouble a week in hospital served to send him back to the fighting line. Between 50 and 60 former patients of the Royal Victoria Dispensary were also on war service.

Ireland.

WESTMEATH AND THE MOTOR AMBULANCE FUND.

At the last meeting of the Westmeath Motor Ambulance Fund it was announced that while £1,871 14s. 1d. had been collected, the expenses connected with the working of the fund had only amounted to £8 2s. 1d. After defraying the cost of two Hotchkiss motor ambulances and paying over £400 to the British Red Cross Society for running expenses, there was a balance of £65. Letters were read from the British Red Cross Society thanking the County Westmeath for its great generosity. No. 1 car, which has now been more than six months on the road, has

been taken over by the Government and has been used to carry the wounded from all the recent engagements; it has frequently been under fire. No. 2 car is still at Boulogne, where it is doing good work, and is being driven by a Westmeath man.

VACCINATION DEFAULTERS.

The Local Government Board has called on the guardians of the Enniscorthy Union to enforce the Vaccination Acts against the 5,343 defaulters in the union area. The guardians decided to ascertain from the doctors what effect the notices recently served on defaulters had produced.

FEVER IN TIPPERARY DISTRICT.

Further cases of typhoid fever are reported from Cullen, in the district of Tipperary. Surprise was expressed at a recent meeting of the guardians when it was stated that one of the patients recently admitted to the hospital was a woman aged 86 years. The sanitary subofficer said that many persons "put the fever over them" and were moving amongst the people without knowing that they had had the disease at all.

INFANT AID SOCIETY.

The Infant Aid Society, formerly known as the Dublin Committee for the Prevention of Infantile Mortality, has for some years been doing unostentatiously a very good work amongst the poorest classes in the city. It can safely be said that if it were not for the work of this society the infantile mortality in Dublin, abnormally high as it is, would be considerably higher. There are over 11,000 babies born in Dublin every year, and at least 660 of these die before reaching the age of 1 year. The notification of births is now compulsory in Dublin, and the object of the Infant Aid Society is to secure that as soon as possible after the notification the homes of mothers in the poorer districts shall be visited by one of the trained voluntary workers. There are about 150 of these trained workers, who during the past year paid over 22,500 visits to the mothers and expectant mothers.

England and Wales.

MR. GILBERT BARLING OF BIRMINGHAM.

On his retirement from the office of surgeon to the General Hospital, Birmingham, after a connexion of thirty-six years, Mr. Gilbert Barling was on December 22nd, at a meeting presided over by the Lord Mayor, presented with an illuminated address and his portrait in oils. Mr. J. E. Willcox (Chairman of the Presentation Committee), speaking on behalf of the 153 subscribers, recalled that Mr. Barling's connexion with the hospital staff began when he was appointed pathologist in 1880, and included the tenure of the office of Dean of the Faculty of Medicine at the University of Birmingham, of which he is now Vice-Chancellor. The hospital, among other debts, owed much to him in respect of the establishment of a pathological department in the hospital. The Lord Mayor accepted the portrait, which is by Mr. E. S. Harper, and will be hung in the board room of the hospital. Mr. W. F. Haslam, senior surgeon of the hospital, then read the address, in which acknowledgement was made of Mr. Barling's invaluable services in the conception, planning, and equipment of the building in which the hospital now carries on its work, and in the promotion of the institution as a medical, surgical, and nursing school. The Lord Mayor, in presenting the address to Mr. Barling, said that the influence he had exercised lay in the force of his personal character, his unselfish consideration for others, and his habit of concentration on any business before him. It was the possession of these qualities, coupled with his skill as a surgeon and administrator, which had earned for Mr. Barling universal esteem, respect, and affection.

Mr. Barling, in his reply, recalled that when he first became connected with the hospital it had one operating theatre, used three or four times a week, while now it had four, used practically every day. The work, too, was of a different character; it used to consist mainly of dealing

with accidents, but now it was more concerned with operations for disease. The revolution which had come over surgical methods was based upon the work of two men—a great Frenchman, Pasteur, and a great Englishman, Lister—to whom was due the safety of patients after operation. Another striking difference was that while in 1880, with about 200 beds, the expenditure on alcohol for patients was £350, now, with 340 beds, all constantly occupied, less than half that amount was spent. Speaking of the new pathological department, he said that people were apt to think that the work of a hospital was limited to giving medicine to sick persons or operating for diseases, but a proper scientific basis for its work was essential. With the new department would lie the future development and success of the hospital; it was essential for treatment in the first instance, and next for the investigation of disease. That typhoid fever, which caused over 10,000 deaths during the South African war, had caused so few in this, was not due to the discovery of a new medicine, but to preventive treatment by inoculation. In conclusion, Mr. Barling expressed his thanks to the subscribers.

Sir John Holder then presented Mrs. Barling with a jewel, as a recognition of the encouragement and sympathy she had given her husband in his long and devoted work to the hospital.

LIVERPOOL MEDICAL INSTITUTION.

By invitation of the Council, the Resident Librarian (Mr. William Jones) read a paper at the last meeting on John Evelyn (1620-1706) illustrated by lantern slides and books from the library of the institution. Mr. Jones showed that the same laudable inquisitiveness set forth in the diary of John Evelyn was still as rife among members of the institution as in the days of the great diarist, but remarked facetiously that it was the rooted opinion of many doctors that no work on medicine was worth reading unless the date of publication was 1915! Evelyn presented to the Royal Society, of which he was a Fellow, Malpighi's work on the history of the silkworm, and the Institution Library possessed also a copy of the works of Malpighi on the anatomy of plants. Evelyn visited Padua, and was present for nearly a month at the famous anatomy lectures by Cavaliere Vestlingius. He brought to England "those rare tables of veins, arteries, and nerves," and presented them to the Royal Society. For this gift Evelyn received the public thanks of the society. Mr. Jones threw on the screen several illustrations taken from Vestlingius and his commentator Blasius—books in the possession of the Institution Library. Evelyn mentions a visit to him of Dr. Tyson, author of a work entitled *The anatomy of a Pygmy compared with that of a monkey, an ape, and a man: wherein it will appear that they are all either apes or monkeys and not men as formerly pretended*. Evelyn's account of how he contracted small-pox in Italy and his description of his sufferings were quoted at length. His host received 45 pistoles of gold and his honest doctor 5 only, who, however, thought the fee so generous that, before leaving, Evelyn received at his hands "the regimen of my health written in Latin"! The diarist visited Leyden, and was present at a graduation ceremony in Oxford, and heard early in the morning Dr. Morison discourse learnedly on divers plants in the physic garden. Dr. Morison was physician to Charles II and Regius Professor of Botany at Oxford. He wrote a book, *Praeludium Botanicum*, a copy of which is in the Institution Library. Evelyn was present at a supper at the Royal Society, prepared in one of Monsieur Papin's digesters, and he alludes to its efficiency—"the hardest bones of beef and mutton being made as soft as cheese." He says, "This philosophic supper caused much mirth amongst us and exceedingly pleased all the company."

Evelyn narrates his visit to Tradescant's museum, which was afterwards bequeathed to Elias Ashmole, a very industrious collector of all manner of curiosities. The collection was finally housed in Oxford in a building erected by Sir Christopher Wren, and Mr. Jones was able to show a pamphlet found during a recent cleaning of the Institution Library, which was none other than a catalogue of the exhibits in the Tradescant's Ark; it was printed in 1666, and is an interesting memorial of the origin of the Ashmolean Museum. Of the dodo, "somewhat bigger

than the largest turkey cock, and so legged and footed, but shorter and thicker," there was a stuffed specimen of this in the Tradescantian Museum. It was unfortunately destroyed in 1775, but its head and right foot were preserved. Evelyn was personally acquainted with Sir Thomas Browne, but Sir Kenelm Digby, of the sympathetic powder, he regarded as an arrant mountebank. Sir Kenelm Digby was a distant ancestor of William E. Gladstone, at whose birth Harry Park, a famous Liverpool surgeon, officiated; his daybook, termed *The Book of Genesis*, records the date of the birth of a Gladstone (M.), Rodney Street, December 29th, 1809. The book was exhibited. Lastly, Evelyn recorded that in 1664, during the war with Holland, he was one of the Commissioners appointed to one of the districts of England to take care of sick and wounded and prisoners of war. He was also one of the Commissioners for the building of Greenwich Hospital, and held the office of treasurer.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

At the meeting of the Governors and Council of King Edward's Hospital Fund for London the honorary treasurer, Lord Revelstoke, stated that the amount received for general purposes to December 11th, after payment of expenses, was £124,575, and that the income from investments for 1915 had, in spite of the difficult times, exceeded that for 1914 by about £14,000. Sir William Collins said that the League of Mercy was again in a position to contribute £14,000 to the fund. Sir Savile Crossley announced that Sir Ernest Cassel proposed to give again, as in 1911, the sum of £50,000 to hospitals, £28,000 to be distributed among the institutions receiving grants from the fund this year, and the remaining £22,000 to be given to certain hospitals and kindred institutions in London and the country. Sir William Church, chairman of the Distribution Committee, announced that the amount available for distribution among the London hospitals was £133,500, being the same as in 1914. Mr. Edwin Freshfield, Chairman of the Convalescent Homes Committee, reported that owing to the fact that some of the convalescent homes which had usually received grants in consideration of their treating convalescent patients from London, had, since the beginning of the war, ceased to take such patients, and had been devoted entirely to the treatment of sick and wounded sailors and soldiers; grants to such homes would not be made this year, and in consequence the Committee had been able to reserve a larger number of beds at consumption sanatoriums for the use of patients in London hospitals and to extend the list of hospitals amongst which such beds are allocated.

Canada.

THE REGULAR *versus* THE IRREGULAR PRACTITIONER.

THE inquiry into the practice of medicine in the province of Ontario was commenced by the Honourable Mr. Justice F. E. Hodgins on October 16th, when over 150 representatives of the various organizations concerned were in attendance. In opening the investigation, Mr. Justice Hodgins stated that he had been delegated to inquire into all the different branches of the medical profession which were seeking legislation for recognition. The organizations represented included the Ontario College of Physicians and Surgeons, the Ontario Medical Association, the Provincial Board of Health, the Medical Faculty of the University of Toronto, the Toronto Academy of Medicine, the Ontario College of Dental Surgeons, the Ontario Optometrical Association, the Christian Scientists, the Osteopaths, the Chiropractors, the Homeopaths, the Drugless Physicians, the Mona Therapists, etc.

The case of the Ontario Medical Association was heard some days later, when an extremely able statement was made by Dr. H. B. Anderson, the president. The association was organized in 1880, and is guided by the following principles: Every person before being legally entitled to treat the sick should comply with the same educational conditions; to understand disease and treat it intelligently necessitates a knowledge of the structure and functions of the body in health, as well as the various conditions acting upon the body to produce change or derangement

of those functions; the arbitrary belief in any special dogma, system, or plan of training can no way relieve the individual from the necessity for this training in the fundamentals of intelligent practice; once the would-be practitioner is properly trained and legally qualified, no restriction should be placed on his freedom to obtain further knowledge of any form of treatment or of the right to practise it. Dr. Anderson said that universities had been provided—for instance, the Provincial University at Toronto, and others—to furnish proper education and scientific training, and that it would be an injustice to every one concerned were illiterate, inferiorly educated, or untrained men given the right to practise. He quoted the following passage from the Report of the Carnegie Foundation (1910, pp. 183-6): "The eight osteopathic schools fairly reek with commercialism. Their catalogues are a mass of hysterical exaggerations alike of the earning and curative power of osteopathy." Quotations were also given from Canniff's *The Medical Profession of Upper Canada* to show that in 1812 "the province is (was) over-run with self-made physicians who have no pretensions to knowledge of any kind. . . . They comprehend not the causes or nature of disease, are totally ignorant of anatomy, chemistry, or botany; many know nothing of classical learning or general science."

On behalf of the Provincial Board of Health, evidence was given by Major J. W. S. McCullough, M.D., provincial officer of health, and by Dr. C. J. O. Hastings, medical officer of health, Toronto. The following suggestions were made by Major McCullough: That the standard of medical education should be maintained and keep pace with the advance in scientific knowledge; that those entering upon the study of medicine should have a good preliminary education, equal at least to honour matriculation; that the course of study should embrace seven years of nine months each; that anatomy, physiology, biology, bacteriology, pathology and diagnosis, as well as clinical experience, should be included in the course of study, no matter what form of treatment any physician desired to pursue; and that no unqualified man or woman should be allowed to practise medicine in any form. He referred to the splendid results obtained at the military camp at Niagara; the water of the Niagara River is perhaps more polluted than that of any other river in the Dominion, yet 20,000 men have passed through the camp where this water is used without a single case of typhoid having been traced to infection in the camp, thanks to the inoculation of the men against typhoid and the other precautions taken.

Dr. Falconer, on behalf of the University of Toronto, also insisted upon the necessity for a thorough training in all the branches of medicine before permission was granted to prescribe for or give any treatment to the sick.

A plea for recognition was made by the optometrists on the ground that at the present time eyeglasses were sold as an ordinary commodity regardless of the condition of the wearer's eyes.

The chiropractors demanded equal status with medical practitioners for graduates of their schools, a certain standard of training for all those granted licence to practise chiropractic, a regular chartered chiropractic institution in Ontario, and a chiropractic board of control. They proposed that a certificate of matriculation, or its equivalent, should be demanded of prospective students, that the course of study should embrace at least three years of nine months each, and that the curriculum should include the study of anatomy, pathology, physiology, chemistry, bacteriology, sanitation, prophylaxis, minor surgery, dietetics, the science of chiropractic and adjunctive therapeutics, such as hydrotherapy, anotherapy, electrotherapy, etc. A similar stand was taken by the osteopaths, both claiming that legislation was required to protect graduates of their schools against impostors.

PROHIBITION IN CANADA.

The war has stimulated the temperance movement in every province, but it is in the prairie provinces of the west that the results have been most marked. In Saskatchewan two bills were passed, and on June 30th 405 hotel bars were closed, the licence was taken away from seven clubs and thirty-eight wholesale liquor stores, and twenty-three dispensaries were established under Government control, which are open between the hours

of 9 a.m. and 5 p.m. Hotels in small places will receive financial assistance during the period of readjustment, and municipal assistance will be given so that rest rooms and libraries may be established in hotels. A referendum will be taken at the first December municipal elections after the war, but not before December, 1916, to decide whether the bars shall be reopened, and in December, 1919, a second referendum will decide the fate of the public dispensaries. Under the present Sales of Liquor Act druggists are allowed to sell alcohol or other liquor only on prescription from a physician, and then only in sealed bottles and during the hours when the dispensary, if such exists, is closed. In Alberta a vote of the people was taken, with the result that temperance gained a majority of 20,000 out of a possible vote of 80,000. Prohibition, however, does not come into force until July 1st, 1916. As yet no arrangements have been made to reimburse hotels, but it is probable that this matter will be adjusted later. In Manitoba the Government was petitioned in 1911 by 20,000 electors to take a referendum on the question of abolishing the bars, and the new Liberal Government has promised to take the people's vote on this question next March. If prohibition wins, no licences will be renewed in the province next May.

In Prince Edward Island there has been total prohibition for fifteen years. With the exception of Halifax, the province of Nova Scotia is "dry," as are more than half of the municipalities of New Brunswick, Quebec, and Ontario. In Quebec a movement is on foot to petition the provincial government to close all bars at 7 o'clock in the evening during the war. It is suggested also that "treating" should be prohibited.

STE. AGATHE SANATORIUM.

At the seventh annual meeting of the Laurentian Society for the treatment and control of tuberculosis, it was reported that 129 patients had been treated at the sanatorium during the twelve months, of whom 87 were discharged. An analysis of the 321 patients treated since the opening of the institution showed that 237 were living. Of these, 170, or 53 per cent., are perfectly well; and 67, or 21 per cent., are fairly well if they take care of themselves. A weekly charge of 8 dollars is made to patients who are unable to pay more, and last year a deficit of 6,000 dollars was met by subscriptions and donations. The citizens of Abbotsford have given \$1,000 to the institution; the amount was collected for the purchase of a machine gun, but diverted to the sanatorium when the Government ceased to accept such gifts. The sanatorium has been placed at the service of the Government for the treatment of soldiers suffering from tuberculosis who have returned from the front. At present twenty-three such patients are under treatment there.

ALBERTA COLLEGE OF PHYSICIANS AND SURGEONS.

The annual meeting of the Council of the College of Physicians and Surgeons of Alberta took place at Edmonton on October 15th. The Council was appointed last July for a period of four years, and consists of one member from each of the seven districts of the province as follows: Dr. John Park, of Edmonton; Dr. F. W. Crang, of Edmonton South; Dr. R. G. Duggan, of Killam; Dr. R. G. Brett (now Lieutenant-Governor of the Province), of Banff; Dr. R. D. Sanson, of Calgary; Dr. G. E. Learmonth, of High River; and Dr. W. S. Galbraith, of Lethbridge. The annual meeting, at its first session, was devoted to business; Dr. F. W. Crang was elected president; Dr. W. S. Galbraith vice-president; Dr. C. W. Field, of Edmonton, registrar and treasurer; and various committees were appointed.

THE first Argentine Congress of Medicine will be held at Buenos Aires in June, 1916.

In the December (1915) number of the *Journal de médecine de Bordeaux* M. René Cruchet gives an account of a "trench journal," the title of which, *Entre les Brancards* (Among the Stretchers), shows that it is devoted to medical matters. It is published under the direction of a distinguished medical officer—J. J. Matignon—and comes out "almost" every week. The contents consist of notes on hygiene with items of news relating to the medical services. The austerity of the *utile* is tempered by a considerable infusion of the *dulce* conveyed in light sparkling verse.

Correspondence.

"MEDICAL CLERKS."

SIR.—As one directly concerned, I read your annotation on "Medical Clerks" with a considerable degree of interest. Your exhaustive criticism of the forms issued under the Mental Deficiency Act (1913) really leaves so little to be said that any remarks I have to make are to be regarded rather as corroborative, and as such may, perhaps, have some value. The filling up of the "Medical Particulars" is, of course, one of the routine duties of the examiner under the Act, and is to be performed in each and every case. Whatever satisfaction may be derived from it by the official mind, it will be admitted that, as a clinical record of a particular patient, it is practically worthless. Apart from the fact, which you comment upon, that the space provided under the different headings bears no relation to their respective importance, it is to be noted that the printed matter actually occupies nearly as much area as that allowed for medical particulars. In most cases there is not even room to answer the question in the simplest terms, and one has perforce to resort to abbreviations. It is as well, perhaps, that the voluminous footnotes—which are highly reminiscent of a railway guide—should state explicitly how the particulars are to be filled in, for where space is so valuable it behoves one to be precise. For instance, under the heading "Teeth," a footnote informs us that the information required is the "number bad." One might have imagined, on general grounds, that in the case of mental defect it would have been useful to have known whether the teeth were "gapped," supernumerary, or irregularly erupted. But, not all that is wanted is the "number bad." No space is devoted to the palate, though one may opine that palatal abnormalities are at least as important as, say, "enlargement of the thyroid" or "fissuring of the tongue." It must be evident, moreover, that many of the queries do not admit of this categorical form of reply—that, in fact, each and all of them may require amplification or qualification in order to be of any value whatever; and for this there is no room. The space devoted to "aetiological factors," again, can only be utilized by reference to a further schedule with no less than thirty-seven subdivisions. It is evidently felt that there is not room otherwise for even the briefest form of answer, so resort is had to a system of symbols to which the schedule aforementioned supplies the key.

When one remembers that the form supplied by the Board of Education for a similar purpose and for the identical class of case is conceived in a totally different spirit and with a true appreciation of the object to be attained, the present document seems all the more inexplicable. If the intention is to alienate the sympathy and interest of the medical man concerned, this seems to be the right way to go about it. If, however, the objective be what it purports to be—namely, the collection and tabulation of authentic data relating to mental defect—surely a great opportunity is being missed. In actual practice, one may assume that the case-book and private record will supplement and complete what the official documents lack, and that in this, as in other branches of medical research, the progress of knowledge will be ultimately dependent upon individual initiative rather than official encouragement.—I am, etc.,

J. E. MIDDLEMISS,
Medical Officer to the Leeds Mental
Deficiency Committee.

Leeds, Dec. 19th, 1915.

BROMIDES IN EPILEPSY.

SIR.—I venture to ask you to allow me to briefly describe my experience in relation to this subject, which includes many years of daily observation of from 90 to 100 cases in the Hanwell Asylum.

Prior to holding my appointment there I had been impressed by seeing two cases of epilepsy, in which by the use of large doses of bromide all fits had been suppressed for long periods, terminate fatally by the occurrence of the status epilepticus. On my taking charge at Hanwell I found bromides in use in very large doses and witnessed several similar terminations, and consequently gave up the use of the drug. At first the number of fits considerably increased, but the irritability of the patients, as

shown in the lessened number of casualties from personal encounters, diminished considerably. The records of fits, however, showed a tendency to diminish in frequency and severity, and in a number of cases ceased altogether as years went on. I have not the slightest doubt that the tendency to dementia in this class of cases was greatly diminished.

In consulting practice I have seen a number of cases, in whom the increasing irritability and excitability under the use of bromide threatened the necessity of control in an asylum, improve on the withdrawal of this drug. I have recently heard from one such case in whom the fits have ceased, and who is now able to take a salaried post.

The withdrawal of the drug must be gradual, or, if sudden, should be accompanied by considerable rest in bed and by abstinence from mental work. I have always to regret the insufficient attention to these precautions in one case in which the severe recurrence of the fits led to a return to the drug treatment. The treatment that I adopted was:

1. Rest in the horizontal position after each attack, from a few minutes to two or three days, the rest being continued until all evidence of undue vasomotor irritability had subsided; this was judged by the irritability of the iris, by the irritability of the pulse on variation of the bodily position, and by the emotionality. By this procedure attacks of maniacal excitement and quarrelsomeness were avoided and the harmful effects of the exhaustion produced by the fits was minimized.

2. Avoidance of mental stress or excitement or emotional stresses, and irritation from digestive or sexual causes.

3. Avoidance of toxic conditions. The diet should be adapted to this end rather than to any theoretical scheme of dietetics, most of which I have tried and found wanting.

Epilepsy is certainly not due to a single set of conditions but to several. In this I quite agree with Dr. Mercier.

Muscular exercise in the open air is probably the most important and valuable means of restoration to health in these cases. Attention to general health on general principles, and not specific drug treatment, is most likely, from my experience, to be successful.—I am, etc.,

London, N.W., Dec. 28th, 1915.

HENRY RAYNER.

THE TONSILS.

SIR,—Dr. Henry A. Barnes in his monograph¹ reaches conclusions which are being increasingly arrived at by those specially engaged in throat work, and it seems time that these simple rules should guide us in our attitude towards the tonsils.

1. We should decide, in dealing with a tonsil, whether the changes in it will yield to simple measures or whether surgical interference is necessary.

2. If surgical interference is necessary, tonsillectomy is the only operation applicable.

3. In reference to the operation of tonsillectomy, or enucleation of the tonsil, a method definite in its result should be adopted—that is, a method by which the tonsil in its capsule complete is definitely removed. This can be performed practically as expeditiously and with as little risk to the patient as tonsillotomy.—I am, etc.,

Glasgow, Dec. 27th, 1915.

W. S. SYME, M.D.

RECRUITING AND DISCHARGE.

The Other Side of the Shield.

SIR,—Your leaderette on "The Medical Examination of Recruits" calls attention to a complaint from medical officers of units at home and abroad of the number of physically unfit men who have been passed as fit for active service. Nothing, however, is said about the enormous number of physically fit men who are daily being discharged from the army for minor defects by these medical officers.

It would be interesting to know how many efficient soldiers have been discharged for small varicocoeles, slight degrees of hammer-toe insufficient to cause discomfort in marching, defects of teeth or inability to satisfy the constantly varying standards of eyesight, height, or chest measurement. Last week a man came to see me who had enlisted early in the war. He had a slight amount of

hammer-toe and a cardiac murmur, with no displacement of apex beat and no sign or history of cardiac inefficiency. He rapidly rose to the rank of sergeant, and he stated that he was never sick, and never had to fall out when on duty. He was discharged because of having hammer-toes. On the strength of this discharge I passed him ("unfit for infantry") for the mechanical transport as a learner. He was again discharged on joining his unit. He was a good soldier, as proved by his rank, a good character shown on his certificate of discharge, and proved to be physically fit by his ability to stand the severe training of Kitchener's army. This is only one of scores or hundreds of cases that have been brought to my knowledge since the beginning of the war.

As to the reputed carelessness of medical officers, I do not believe it exists to any great extent. It is not remarkable that early cases of tuberculosis should be missed; it is almost a miracle that any should be discovered considering the conditions under which the work has had to be done during the several periods of rapid enlistment, and particularly in the early days of the war and during the first fortnight of this month.

In this town, although every civil practitioner was asked to help (most of them willingly doing so), and although many fresh centres were opened to cope with the rush of recruits, yet it was not uncommon for a doctor to have to examine from eighty to a hundred men a day in a noisy and crowded room.

Among the cases you mention are the chronic epileptics. Can the R.A.M.C. officer diagnose epilepsy in a man who appears intelligent and who denies having had fits? I do not profess to be able to do so. Deformities of limbs are passed sometimes; after all, the army is not a beauty show, and the appearance of a man on parade is not everything. I remember passing a man who had lost the trigger finger of his right hand. He was a gamekeeper, and a most excellent shot.

You mention also cases of hernia. The medical officers of this town were definitely instructed by the colonel inspecting the district that inguinal hernias could be passed for home service if small and capable of being kept up by means of a truss.

You also particularly mention the standard of fitness in the foot. I passed a man with a slight degree of flat-foot, who was promptly discharged on joining his unit. Up to the time of his enlistment he was a professional football player in an Association team.

If men are passed as fit and prove unfit for their work they should be discharged, but it is nothing less than a grave scandal that good and fit men should be discharged for minor defects without giving them a trial, and in my opinion it is better and cheaper that many unfit men should be passed into the army rather than run the risk of losing even a comparatively small number of good soldiers.—I am, etc.,

December, 1915.

CIVIL EXAMINER OF RECRUITS.

MEDICAL STUDENTS AND THE INSPECTION OF RECRUITS.

SIR,—May I draw the attention of the governing bodies of medical schools in the three kingdoms, and in Australia and Canada, to the desirability of giving medical students, in their fifth year of study, the opportunity of seeing the actual physical examination of recruits for the army being carried out by the trained medical recruiting officers? There are large recruiting centres in the localities where medical schools exist, and if an application were made to the local recruiting officers, no doubt permission could be obtained. Further, it is possible that two or three lectures could be given to the advanced students each session by the official recruit inspector.

The gain would be great to the students, and to the army, navy, and, indeed, all services where a physical test is needed for entrance.

I often wonder why the associated insurance companies of England do not pay a specialist to go round the medical schools and lecture the advanced students on the insurance inspection routine standard of the various companies. It is to be remembered that we train our students on the morbid conditions of the body; why not let them see the human physique in all its varying health conditions?

One would imagine that the first diploma a man should

¹ BRITISH MEDICAL JOURNAL, October 16th, 1915, p. 569.

take would be the public health diploma of perfect health conditions, and other diplomas as to cure should follow in sequence. "The best wealth is health."—I am, etc.,

London, S.W., Dec. 24th, 1915.

G. J. H. EVATT, M.D.

POISONING BY CHLORINE.

SIR,—Advertising to Dr. Hill's paper on the phenomena of chlorine poisoning, it is worthy of note that Sir Charles Cameron of Dublin found chlorine very definitely in the lateral ventricles of the brain in a case of chlorine poisoning which he examined many years ago.

The case in question was that of a man who had been in a small room into which a quantity of chlorinated lime had found its way whilst he was asleep. Cameron's examination took place thirty hours after death, and the odour of chlorine found in the ventricles was quite remarkable.

Dr. Hill's account of the exudation of an albuminous fluid into the alveoli of the lungs, as a usual sequence of the inhalation of chlorine, agrees very closely with the description given by the soldiers who have been "gassed" in Flanders. The sensations are described as like those of a drowning man, and "dryland drowning" was the popular term applied to the symptoms.—I am, etc.,

J. C. MCWATER, M.D.,

F.R.F.P. and S.Glasg., Lieutenant R.A.M.C.(T.).

Dublin, Dec. 18th, 1915.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following degree has been conferred:

D.M.—H. T. Evans, Jesus Coll.

The following candidates have satisfied the examiners in the undermentioned examinations:

FIRST B.M., B.Ch.—*Organic Chemistry*: G. Aldred-Brown, P. Boobbyer, W. Boone, T. Brown, R. Emmons, E. Liddell, W. Allan-Row, T. Ryves, N. Smith, H. Toms, E. Watkins. *Anatomy and Physiology*: E. Crook, W. Gover, C. Krige, R. Roberts, G. Stone, E. Woods.

SECOND B.M., B.Ch.—*Pathology*: J. Blamey, E. Creed, L. Davies, W. Dawson, G. Perkins, C. Sells, N. Sprott. *Forensic Medicine and Public Health*: A. Traill, A. Watts, T. Whitcombe. *Materia Medica*: L. Davies, J. Walker. *Medicine, Surgery, and Midwifery*: G. Bowes, L. Davies, A. East, L. Gamson, G. Gimlette, H. Jeffries, M. Lawrence, H. Oddy, C. Sells, A. Traill, T. Whitcombe.

D.P.H.—*Part I*: E. F. Butler, J. T. MacManus, R. H. Vercoe. *Part II*: E. B. Argles, T. R. Bowen, E. G. Brander.

UNIVERSITY OF CAMBRIDGE.

THE following degrees have been conferred:

M.B.—W. F. Bensted-Smith, E. N. Butler, J. D. Clarke, H. G. Hill. B.C.—E. N. Butler, J. D. Clarke.

The following candidates have been approved at the examinations indicated:

M.C.—A. T. Edwards, R. A. Ramsay, L. C. Rivett.

FIRST M.B.—*Part I, Chemistry*: G. F. Abercrombie, F. H. S. Calger, W. R. Carling, H. A. Crowther, N. D. Duncombe, F. R. G. Hief, P. B. Kittel, R. J. Lythgoe, F. Miller, D. G. Sharp, S. D. Sturton, W. S. R. Thomas, H. B. Yates.

Part II, Physics: A. Barker, A. Carling, H. A. Crowther, N. D. Duncombe, G. S. W. Evans, F. R. G. Hief, F. B. Hobbs, E. J. Lythgoe, E. Miller, R. Y. Paton, J. Russell, D. G. Sharp, S. D. Sturton, W. S. R. Thomas, A. D. Whitelaw, H. B. Yates.

Part III, Elementary Biology: G. F. Abercrombie, A. Barker, W. R. Carling, G. S. W. Evans, F. B. G. Hief, P. B. Kittel, R. J. Lythgoe, E. Miller, R. Y. Paton, A. D. Porter, A. E. Roche, J. Russell, D. G. Sharp, J. L. Strain, W. S. R. Thomas, M. H. Webb-People, C. H. Whittle, A. W. Wilson, H. B. Yates.

SECOND M.B.—*Part I, Human Anatomy and Physiology*: W. F. Attwater, H. Barbash, L. H. Bartram, P. F. Bishop, E. P. Brookman, H. B. Bullen, W. M. Casper, S. P. Castell, C. B. Cohen, E. J. Crisp, E. C. Curwen, R. W. M. Dendy, C. C. B. Downing, C. H. Gunasekara, A. C. Halliwell, G. G. Havers, A. T. Hawley, W. M. Heald, T. L. Hillier, S. C. Ho, J. M. Lawrie, J. R. Mitchell, P. M. Neighbour, R. A. Oliphant, F. P. N. Parsons, E. H. Reece, R. H. O. B. Robinson, A. T. Spoor, H. F. Squire, W. S. Sykes, M. S. Thomson, J. P. Wells, D. E. Wijewardene, R. L. Williams, D. W. Winnicott, F. G. Wood, J. M. McC. Wright.

THIRD M.B.—*Part I, Surgery and Midwifery*: G. A. Back, S. L. Bhatl, H. V. Deakin, A. N. Drury, C. Gardiner-Hill, S. H. M. Johns, R. F. Jones, W. N. Leak, F. New, S. E. Pralle, M. K. Robertson, *H. W. Scott, G. E. Spicer, N. S. Tirard, F. H. Young.

* Surgery only.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

M.D.—BRANCH I (Medicine): A. S. Erulkar.

BRANCH IV (Midwifery and Diseases of Women): Lillas M. Blackett, Dorothy C. Logan.

SECOND EXAMINATION FOR MEDICAL DEGREES (Part I).—*Marjorie Back, J. Brodetsky, *Kathleen M. Cogan, Doris M. Howard, A. St.G. J. McC. Huggett, Muriel M. Kenworthy, Jessie C. Ritchie, Joan M. Ross, Ethel N. Thomas.

* With distinction.

UNIVERSITY OF EDINBURGH.

THE following candidates have been approved at the examination indicated:

PRACTICAL MATERIA MEDICA.—Catherine J. Anderson, E. Arosemena, G. S. Bainbridge, I. O. C. Barclay, W. T. Benson, E. Obonglop, A. C. Y. Chow, J. A. L. Cook, J. H. Crawford, D. A. Cunningham, A. A. Denham, Kshirendra M. Dey, E. D. D. Dickson, H. J. A. Dingwall, J. K. van O. Duminy, G. W. Dunlop, M. A. P. B. Eaton, B. A., W. Everett, D. Fergusson, G. S. Freeman, B. N. Gibson, H. A. E. Girby, Alice M. Graham, O. Gray, Jeannie J. Harper, T. L. P. Harries, W. H. Herberg, R. A. S. Hoyte, W. G. Hughes, N. W. Johnston, J. H. Kerr, J. I. Kuit, J. L. Lamont, B. A., G. Lange, M. Lipschitz, C. M'Donald, R. B. MacGregor, H. B. Mackenzie, R. N. Mackenzie, A. W. Mackie, J. M'Nab, J. M. Macpherson, W. E. Mathewson, G. H. H. Maxwell, M. Melvin, J. S. Moroka, T. B. Moyes, J. M. S. Nichol, H. J. Parish, E. G. H. Payne, H. S. Percival, F. W. Poole, D. Rankin, J. Rauch, Dorothy A. Robertson, W. G. Robson, M. Sash, C. E. Scott, Mahmoud Z. Sheriff, C. Stimpson, D. W. Sinclair, G. M. S. Smith, Janet S. Smith, Marguerite B. Stirling, E. B. Thounissen, J. L. Timothy, D. L. M. Tod, A. E. P. Vanier, P. F. V. Walsh, J. S. Westwater, J. L. Wilson, W. L. Zeeman.

UNIVERSITY OF ST. ANDREWS.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—Ram Nath Bhandari, T. P. Buist, Louise E. Fraser, C. W. Morrison, A. A. B. Scott, J. M. Stalker. THIRD PROFESSIONAL.—*Materia Medica and Therapeutics*: F. J. Charlton, J. MacD. Clark, Mary I. S. Cuthbert, Kathleen I. David. *Pathology*: F. J. Charlton. D.P.H.—*First Examination (Chemistry, Physics and Meteorology, and Bacteriology)*: A. O. Craighead. *Second Examination (Sanitary Law and Vital Statistics, and Practical Sanitation and Epidemiology)*: K. M'Leay.

UNIVERSITY OF DUBLIN.

At the Winter Commencements held in Trinity College on December 20th the following degrees were conferred:

M.B., B.Ch., B.A.O.—D. H. Hall, T. W. G. Johnson, G. F. L. Murphy, F. W. O'Connor, R. L. Vance. M.D.—B. D. Crichton; *in absentia*, Rev. E. E. Lavy. M.Ch.—A. Chance. L.M., L.Ch., L.A.O.—*In absentia*, T. E. B. Beatty.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

The following candidates have passed the examinations indicated:

PRELIMINARY SCIENTIFIC.—*Chemistry*: D. H. G. Fishbourne, H. A. Lavelle, J. C. J. Callanan, W. J. Hogan, E. W. Harris, G. R. L. Jordan, J. G. Holmes, Mayo Frances Meade, E. H. Montgomery, J. F. Van Staden, S. J. Laverty. *Physics*: C. W. Parr, T. F. L. Cary, G. R. L. Jordan. *Botany and Zoology*: J. F. Sheppard, V. G. Walker, R. D. Murphy, J. G. Holmes, D. H. G. Fishbourne, Eileen H. Dowse, P. J. Healy, A. V. Foster, H. C. Dundon, E. H. Montgomery, P. J. Duggan.

INTERMEDIATE MEDICAL.—*Part I (Anatomy and Physiology)*: E. J. Lyndon, W. F. McConnell, John B. McGranahan, C. Keller, W. L. Young, P. A. Dornier, K. Greer, J. M. Hill, T. Tabuteau, J. Posner, D. McElwee, F. J. Dymoke, F. W. Godbey, J. A. W. Cullen, J. G. Bird.

Part II (Applied Anatomy and Applied Physiology): C. G. Ambrose, F. C. Parr, Margaret Wolfe, P. Casey, W. J. Hamilton, J. E. Hill, Meta G. Jackson, F. J. Dymoke.

M.D.—B. D. Crichton, Rev. E. E. Lavy.

M.Ch.—A. Chance (high marks).

FINAL MEDICAL.—*Part I (Medical Jurisprudence and Hygiene, Materia Medica and Therapeutics, and Pathology)*: A. H. Davidson, W. F. Wicht, F. A. Hall, W. Garde-Browne, J. G. Bird, R. W. Prichard, J. P. Macnamara, J. B. Taylor, *H. H. Molloy, *M. Hamilton-Johnstone, *M. C. Dipponaar.

Part II (B.A.O., Midwifery and Gynaecology): J. W. Bigger, T. P. Chapman, E. C. B. Ramsay, Clotilda B. Bevis, R. M. B. Gordon, F. W. O'Connor, W. Garde-Browne, P. A. Hall, C. L. McDonogh, W. L. Bates.

* Pathology, Medical Jurisprudence, and Hygiene. † Pathology. ‡ Materia Medica, Medical Jurisprudence, and Hygiene.

FINAL.—*Part II (B.Ch., Surgery)*: T. W. G. Johnson, G. W. Doran, T. E. Beatty, F. W. O'Connor.

Part II (M.B., Medicine): A. F. Grimby, E. Lipman, F. J. Murphy, R. L. Vance, Esther V. Adderley, Marie A. Hadden, D. H. Hall, Violet M. Deale, G. L. Murphy, F. W. O'Connor.

SPECIAL FINAL.—*Part II (B.Ch. Surgery)*: Geraldine Murphy, H. Mitchell, C. McI. West, W. F. Wilson, C. G. Sherowitz, W. B. Walker, G. Bateman, T. W. Sweetman, R. L. Vance, R. H. Graham, J. H. O. Walker, D. H. Hall, G. L. Murphy, W. Hunt, A. G. Fisher.

Part II (M.B., Medicine): T. W. Sweetman, H. Mitchell, Clara B. M. Adderley, C. G. Sherowitz, E. Mannin, T. E. Beatty, B. H. Graham, W. Hunt, A. G. Fisher, M. B. King.

Part II (B.A.O., Midwifery and Gynaecology): J. A. C. Kidd, J. M. Ryan, M. A. Hadden, A. F. Grimby, L. Blumberg, Eileen G. Gwynn, T. G. Roche, E. Boyers, W. Hunt.

D.P.H.—*Parts I and II*: Ratan Edulji Dastur.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates were approved at the examination held at the close of the forty-ninth session:

*V. A. Goonetilleke, M. de Costa, †T. Ryan, E. J. Rowbotham, R. J. Tata.

* Ceylon Military Service. † West African Medical Service.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

SURGERY.—*A. Z. Abushady, *R. N. Craig, *C. B. De Forest, *W. Fox, *J. Kahau, *I. H. Lloyd, *J. S. Matthews, *A. W. North, *I. H. Pearse, *E. F. Samara-weera, *J. G. T. Thomas, *M. M. M. *W. F. R. Castle, *R. N. Craig, *W. J. May, *G. S. Mitchell, *A. W. North, *I. H. Pearse, *T. C. Russell, *R. H. Yolland.

FORENSIC MEDICINE.—W. F. R. Castle, R. N. Craig, G. S. Mitchell, I. H. Pearse, C. G. Winter, R. H. Yolland.

MIDWIFERY.—R. N. Craig, I. H. Lloyd, I. H. Pearse.

*Section I.

†Section II.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery: A. Z. Abushady, R. N. Craig, W. Fox, I. H. Pearse, and E. F. Samara-weera.

Medico-Legal.

CHARGES FOR WATER FOR WASHING CARS.

SOME doubts appear to exist among medical men as to their liability to meet special charges which are made in most districts by water companies for the supply of water used for the washing of motor cars and carriages.

The answer as to liability depends upon the powers conferred upon each particular company. Like railways, tramways, and undertakings of a similar nature, a public water supply of any magnitude can only be constructed and worked with the authority of Parliament, which passes a special Act dealing with the powers and liabilities of each undertaking which it is proposed to construct. It therefore follows that the powers of individual water companies, and the charges they are entitled to make, will vary. Under the Waterworks Clauses Act, 1847, the undertakers who seek parliamentary powers must be prepared to provide and keep in their mains a supply of pure and wholesome water sufficient for the domestic use of all the inhabitants of the town or district for which the supply is intended, and although this domestic supply is usually charged upon a fixed basis, a special Act may sometimes provide that even domestic supply water may be charged by meter. Assuming, however, that a particular company charges for water supplied for domestic purposes at a fixed annual sum varying with the rateable value of the premises supplied, the occupier is entitled to the use of the water for the ordinary and reasonable purposes of domestic life, and the company is not entitled in the absence of special provision in its special Act to make further charges for such uses as for baths, waterclosets, the watering of gardens, or the washing of carriages kept for private use. Where, however, water is used for trade purposes, water companies are almost universally empowered to make a special charge.

It was decided in a case brought by the Harrogate Corporation in 1907 that water used for washing a carriage or motor car used by a medical man in connexion with his practice was not used for a trade or business, and the sole question therefore is as to whether in each individual case the water company has parliamentary powers to limit the uses of water supplied for domestic purposes, and to make a special charge in respect of water used for motor cars.

This, as we have pointed out, can be ascertained, and can only be ascertained, from the terms of the Act of Parliament by which any individual water company is governed, and any medical man upon whom this charge is made, and who is in doubt as to his position, will do well to ask his water company for their authority. Until 1907 the Metropolitan Water Board had no power to make such a charge, but in that year they sought and obtained from Parliament additional powers to make it; and, so far, therefore, as the metropolis is concerned, the charge is one which cannot be resisted. No doubt other water authorities and companies have in a large number of cases followed suit.

Obituary.

LIEUTENANT-COLONEL L. F. CHILDE, I.M.S.,

FORMERLY PRINCIPAL OF GRANT MEDICAL COLLEGE, BOMBAY.

We regret to announce the death of Lieutenant-Colonel Letterstedt Frederick Childe, I.M.S., which occurred on December 14th while on a visit at Southsea to his brother, Lieutenant-Colonel C. P. Childe, R.A.M.C.(T.), Senior Surgeon to the Royal Portsmouth Hospital. Lieutenant-Colonel Childe had been in indifferent health for the past three years, the result of long and arduous service as professor at the Grant Medical College, Bombay, and also as physician to the Jamsetjee Jeejeebhoy Hospital in the same city.

Lieutenant-Colonel Childe received his medical education at Guy's Hospital, and graduated M.B.Lond. in 1885. He entered the Indian Medical Service in March, 1887, taking a high place in both the entrance

and the Netley examinations. He arrived in India in November of the same year, and was posted to Poona on general duty. After a short stay at Poona he was appointed to the officiating medical charge of the 12th Bombay Infantry at Ahmedabad, where he remained until the end of 1888. He then proceeded to the medical charge of the 8th Bombay Infantry at Rajput, and shortly after went with this regiment to Pishin, in Baluchistan, on the North-West Frontier. At the end of 1889 he was summoned to Bombay to take up duties as professor of pathology and curator of the museum at the Grant Medical College, as well as those of the second physician at the Jamsetjee Jeejeebhoy Hospital. In this appointment he worked up to the year 1902, when he was promoted to be professor of medicine and first physician of the same institutions.

In March, 1913, he succeeded in addition to the principalship of the Grant Medical College and the senior medical officership of the Jamsetjee Jeejeebhoy Hospital. He put in much arduous service in these institutions with which he was so long connected, and his labours were particularly trying in the early years of the great plague epidemic in Bombay. To him belongs the credit of being the first to recognize and describe the pneumonic form of plague, and his original description of this form of the disease holds good to the present day. Colonel Childe's name will long remain in the memory of the medical profession of Bombay, among whom are many who were his pupils and who owe much to his teaching. He particularly shone as a clinical teacher, and "Dr. Childe's clinics" were greatly appreciated and followed with the keenest attention by his students. As a consultant Lieutenant-Colonel Childe was highly thought of for his deliberate and very sound judgements. He was a man of few words, but when he spoke it was always to the point, and it was certain that his opinions were based on sound logical grounds. The writer of this memoir is a friend of long standing, and he and a host of other old friends deeply mourn the death of one for whom they had a great affection. Lieutenant-Colonel Childe had only recently retired from the Indian Medical Service, and it is very sad that he did not live to enjoy the years of his well-earned rest with his family in England. Colonel Childe was the second son of the late Rev. G. F. Childe, formerly professor of mathematics of the South African College, Cape Town. He was born in South Africa in the year 1859, and received his school and college education in that country, coming to England in the year 1878 and entering as a student at Guy's Hospital.

He married Edith, the daughter of the late Mr. A. Murray, formerly manager of the Bank of Bombay, by whom he leaves two sons and two daughters.

We regret to announce the death of Dr. M. C. MOLONEY, J.P., which took place at his residence, Tulla, on December 4th. Though he had been ailing for some time his death occurred suddenly. Dr. Moloney was a student of the Royal College of Surgeons in Ireland, and became a Licentiate of the College in 1881. After practising for a few years in London he was appointed medical officer to Tulla Workhouse Infirmary and Fever Hospital, which post he held to his death. He was a justice of the peace for co. Clare, where his family had been well known for many years. There were few doctors in Munster who occupied a higher place in the esteem of his professional brethren than Dr. Moloney, and his skill no less than his cheery manner made him beloved by his patients. His death is deeply felt by all the people in his district, rich and poor alike, and a personal loss to many of his profession.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Homer G. Newton, one of the founders of the Brooklyn Eye and Ear Hospital, and an early specialist in diseases of these organs in Brooklyn, New York, aged 79; Dr. William Noyes, formerly superintendent of the Boston Insane Hospital and clinical instructor in Harvard Medical School, aged 58; Dr. Henri Parmentier, president of the French Medical Committee and chief physician to the auxiliary hospital of the National Federation; Dr. Potiquet, of Paris, well known by his psycho-physiological studies of Madame Récamier,

Chateaubriand, and other literary, social, and political celebrities; Dr. Schmidt-Rimpler, sometime professor of ophthalmology in the University of Halle, aged 77; Dr. Ville, professor of medical chemistry and pharmacology in the University of Montpellier, aged 66; and Dr. Camille Vincenti, lecturer on hygiene in the University of Rome, editor of the *Avvenire Sanitario*, aged 52.

The Services.

EXCHANGE DESIRED.

CAPTAIN, Field Ambulance, desires exchange with another officer at Casualty Clearing Station, General or Stationary Hospital, B.E.F. Address No. 6050, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Medical News.

THE next meeting of the Medical Society of London will be held on Monday, January 17th, when a discussion on gunshot wounds of the chest will be introduced by Colonel Sir John Rose Bradford, F.R.S., and Captain H. Morriston Davies, F.R.C.S.

AT the meeting of the Surgical Section of the Royal Society of Medicine on February 2nd, at 5.30 p.m., Dr. Hernaman-Johnson will give a demonstration of the use of condensers in the treatment of nerve lesions.

THE General Superintendent and Secretary of the Manchester Royal Infirmary asks us to state, for the information of those who have been connected in any way with the infirmary, that it is proposed to raise a fund to commemorate the memory of Sister French, who died on November 20th, after thirty-five years of loyal and devoted service. It is hoped to complete the panelling in the chancel, and to place a tablet in her ward.

THE Cornell University Medical College, New York, has recently reorganized its surgical service at Bellevue Hospital. At the head of it there is now one "visiting surgeon in charge," who has general supervision over the entire work. There are two visiting surgeons, who also have a continuous service limited to some special subdivision of general surgery. Under the visiting surgeon in charge are two associate visiting surgeons, who are full-time salaried officers; each has the care of one-half of the service. They have as assistants four juniors, who are also surgeons to the out-patient department. The organization also includes a laboratory of surgical pathology and a laboratory of experimental surgery, each under a full-time salaried man. These laboratories are available to all members of the staff, who there have the privilege of working on their individual problems.

THE Factory and Workshop Act, 1901, Section 73, required every medical practitioner attending on or called in to visit a patient whom he believed to be suffering from certain conditions, which were enumerated, contracted in any factory or workshop, to send to the Chief Inspector of Factories at the Home Office, London, a notice stating the name and address of the patient and the nature of the disease; the fee for making this service is 2s. 6d. Should he fail to send such notice he becomes liable to a fine not exceeding 40s. The Home Secretary has now made an order, which comes into force this day (January 1st), applying the provisions of the section to all cases of *toxic jaundice* occurring in a factory or workshop—that is, jaundice due to tetrachlorethane or nitro- or amido-derivatives of benzene or other poisonous substance.

THE Paris Académie des Sciences, at a meeting held on November 29th, 1915, awarded the Le Conte prize, of the value of £2,000, to Sir Almroth Wright for the part taken by him in the introduction of antityphoid vaccination into medical practice. Among other prizes awarded at the same sitting were the Jecker prize of £400, given to M. Gabriel Bertrand, of the Pasteur Institute, for his chemical researches; the Lallemand prize of £40, given to Dr. Jules Glover for a treatise on the physiology of the voice applied to art and industry; and the Montyon prize of £30, given to Dr. André Thomas for his researches on cerebellar localizations. The awards of the prizes of the Académie de Médecine were announced at a meeting held on December 16th, 1915. Owing to the war the number of candidates was much below the average, and several of the most important prizes were not awarded, while many of the others were divided.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2531, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Atiology, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

ANSWERS.

J. D. writes in reply to a question by "S." regarding snoring, and suggests (1) the thorough examination of the nasal passages and the removal of any obstruction to normal respiration; (2) the correction of any acquired habit by wearing a suitable chin support to prevent mouth-breathing at night.

ADRENALIN IN ASTHMA.

W. M. C. writes, in reply to N. S. C., who asks for particulars of experience of the use of subcutaneous injections of adrenalin in asthma: I have been using adrenalin (Parke, Davis and Co.) 1 in 1,000 solution for subcutaneous injections for asthma for the last four years. I begin with 5 minims and gradually work up to 10 minims. I do not inject until the breathing is pretty bad. I have injected it eight times in twenty-four hours (10 minims each dose), but three and four times a day was about the average. After injection the patient becomes deadly pale and feels faint, and there are slight muscular tremors, or trembling of the hands, for about an hour. The breathing is relieved immediately. Twice my patient suffered badly from symptoms of impending death. Great pallor, faintness, and acute pain at the base of the brain, following immediately after the injection. The administration of a little brandy brought the patient round. I have also found the following powder of great use when I wished to discontinue the adrenalin: Thiobrom. sod. sal., gr. viij, caffeine valer., gr. iv. It is taken in water; it has a very disagreeable smell, but a not unpleasant bitter aromatic taste. The patient gets relief in about an hour, and is again able to lie down. After adrenalin the patient should rest for about an hour. This treatment does not cure, only relieves. At present I have a patient under treatment with a serum made from germs from his nose, throat, and sputum, and after eleven injections—one a week—he is now almost free from asthma.

DR. W. H. SPURGIN (Newcastle-on-Tyne), who writes that he has had considerable experience in the administration of adrenalin, suggests the injection of adrenalin sol. m x, morphine gr. $\frac{1}{2}$ every night, increasing the morphine as required.

LETTERS, NOTES, ETC.

PHYSIOLOGICAL CARDIAC IRREGULARITY.

DR. WILLIAM BRAMWELL (Liverpool) writes: Sir James Mackenzie's amusing account of his difficulty in convincing a medical practitioner that there is such a thing as physiological cardiac irregularity reminds me of a lady aged 89 whom I last saw a year ago and whom I have attended at intervals during the last eighteen years. All her life she has been the subject of the most remarkable cardiac irregularity I have ever examined. A succession of irregular beats, sometimes quick and sometimes slow, would be followed by the most alarming pauses such as would beguile the majority of practitioners not acquainted with her idiosyncrasy into warning her relatives of her approaching dissolution. The only sign, however, of cardiac insufficiency besides that ascertained by auscultation and palpation—there being no indication of murmur or valvular deficiency—was that her cheeks and nose were surcharged with minute venules, which gave a slight appearance of cyanosis. She had, however, eyes of piercing brightness, which seemed to rival the vivacity of youth in clearness and quickness of movement; and without the slightest indication of breathlessness she would talk for long periods in a deliberate and domineering manner, which would brook no interruption, one of her chief delights being the indulgence in a little biting sarcasm at the expense of certain luckless physicians who had ventured to remark that all was not right with her heart. This case, at any rate, will show that it is quite possible for extreme irregularity of heart to last through a long life and be compatible with a healthy and even a vivacious old age.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

RESEARCHES ON PHAGOCYTOSIS.

BY

H. J. HAMBURGER, Sc.D., M.D., LL.D., F.R.S.,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF GRONINGEN (HOLLAND).

I. INTRODUCTION.

THE investigations on the life of phagocytes, which during recent years have occupied myself and my collaborators, are a continuation of researches begun several years ago (1883) with the object of ascertaining the influence of salt solutions of various concentrations upon the red blood corpuscles, and the significance of these results with regard to the functions of the body. These researches on the red blood corpuscles, which introduced physical chemistry into medical science, were confined to the study of their chemical and volumetrical alterations.

But the influence of the salt solutions on the very life of the cells could not well be tested on those particular objects, although systematically investigated. We have felt this from the beginning, and repeatedly asked ourselves whether the solutions producing the chemical and volumetric changes of the red blood corpuscles had or had not seriously damaged these cells, and thus, whether it was possible to apply the conclusions arrived at to problems regarding life itself. Therefore, wherever it was possible, we examined whether the phagocytes, being submitted to the same agencies, kept their phagocytic power. This was always the case. This conclusion enhances the value of our researches on red corpuscles, the more so because the chemical and volumetric alterations of the white cells corresponded with those of the red. But a systematic study of the life of leucocytes had not, previous to our researches, been undertaken, and this is rather surprising.

The phagocytes are a suitable object for studying life phenomena. In the first place, they are not such complicated organs as the muscles, heart, brain, etc.; they are simple cells, easily isolated. Secondly, it is possible to follow quantitatively the effect on their life of slight alterations of their natural medium.

It is obvious that the phenomena produced by the agency of solutions not dangerous to life are, in fact, nothing else but the effect of reactions which finally will help us to penetrate further into the physical and chemical structure of the living cell.

Yet not only from a theoretical but also from a practical point of view the life of these cells deserves our interest; but until now it has not been, as such, the object of a systematic investigation, a fact Metchnikoff himself regretted in a paper he read some years ago to the students of the University of Amsterdam, on "Réactions Phagocytaires":

Nous ne sommes qu'au début. Lorsqu'on connaîtra mieux la physiologie des phagocytes, on cherchera des méthodes pour augmenter l'activité de ces éléments dans la lutte contre les microbes, et on cherchera d'autres pour préserver contre l'attaque des phagocytes les cellules nobles de notre corps.

Now I must confess that the importance of the phagocytes for the defence of our body against bacteria has not been the first and principal reason of my investigations with regard to these cells: the principal reason was that they were an excellent object for researches of a general biological nature.

I think a physiologist in the first place must practise science for its own sake, not asking whether his work may be of immediate practical use; but should he, however, accidentally stumble upon an idea which may be directly used for the bodily welfare of mankind, this should not prevent him from giving his attention thereto—in fact, it is his duty to do so.

II. METHOD OF INVESTIGATION.

Our method has been very simple. White corpuscles (leucocytes) from the blood of a horse are transferred to various media mixed with very small particles of carbon. After having stood some thirty minutes in an incubator at body temperature a great many of the cells have eaten up carbon. Microscopical preparations are made, and it is ascertained what percentage of the leucocytes has taken up carbon. *This percentage is the measure of the degree*

of phagocytosis, and gives the value of the influence of the various agents used on that function of life.

Suppose in examining 600 leucocytes lying in their natural medium I find that 300 of them have taken up carbon, the percentage of phagocytosis can then be expressed by $\frac{300}{600} \times 100 = 50$ per cent. In order to examine, for instance, the influence of small amounts of acid, I add this substance to the serum and repeat the same experiment under the same conditions. I now find that of the 540 examined leucocytes only 200 have taken up carbon. The phagocytosis is now expressed by $\frac{200}{540} \times 100 = 37$ per cent. Thus the addition of acid to the serum has lowered phagocytosis.

This calculation is based on the principle that the phagocytic power of the individual phagocytes present in a suspension is unequal, a fact which cannot be wondered at when we take into consideration that they are of different ages. The more detrimental the action of the agent the smaller should be the number of phagocytes which take up carbon in the same space of time.

Our selection of an indifferent substance such as carbon instead of bacteria was based upon the fact that we feared our work would otherwise become too complicated. We here refer to the fact established by Sir Almroth Wright and his school that most kinds of bacteria, before they can be taken up by the phagocytes, must undergo a certain amount of sensitization. Hence it follows that the intensity of phagocytosis will not only be influenced by the agent, as such, but also by the degree of "sensitization" the particles have undergone. Another fact which had to be borne in mind was that bacteria sometimes secrete poisons, which have an injurious effect on the phagocytosis. Even dead bacteria contain poisons.

The selection of carbon as an indifferent substance instead of the usual grains of carmine was based upon the greater facility and accuracy with which the taking up of carbon can be ascertained. I shall not give here a detailed description of the method of obtaining the leucocytes or of preparing the carbon, or of the method of determining the percentage of cells which have eaten carbon. I prefer to give some of the more striking results. A glance on the figures in the tables will give an idea of the exactitude of the method, an exactitude which cannot be obtained with bacteria.

III. RESULTS.

1. The Influence of Small Amounts of Calcium.

In examining systematically the influence of the addition of small amounts of various salts (ions) to the blood serum, it was found that very small quantities of calcium increased the phagocytosis to a considerable extent. An addition, for instance, of 0.005 per cent. of calcium chloride (CaCl_2) to the natural medium (serum) caused an increase of about 22 per cent. in the phagocytic power. This favourable effect becomes even more strongly manifest when, instead of being added to the suspension of phagocytes in serum, the calcium is added to a suspension of phagocytes in a solution of sodium chloride (common salt) in which phagocytosis occurs almost to the same extent as in serum.

These investigations have been continued in two directions. In the first place, we asked ourselves whether the influence of calcium would also manifest itself in the living body. All experiments had hitherto been made outside the body. It will be remembered that on placing under the skin (for instance, on the inside of the thigh of a rabbit) small capillary tubes, closed at one end and filled with an extract of bacteria in a solution of sodium chloride, phagocytes enter these tubes. Chemotaxis is based upon the creeping movement of the phagocytes towards the excretions and secretions produced by the bacteria.

After a certain lapse of time the open part of the capillary tube is filled with a white column consisting of phagocytes. If, in fact, calcium promotes the activity of the phagocytes not only in the phagocytic process described above, but also in the living body, we argued it might be expected that by calcium that mobility of the cells, which here finds its expression in chemotaxis, would be accelerated. Therefore we determined the length of the white column formed in the capillary tube

with animals, either treated with calcium or not so treated.

We expected to find that in rabbits treated with calcium the white column would, after the same space of time, be longer than in animals not having been treated with calcium. We have used two methods, which gave the same result. I will mention only one. It consisted in injecting into the rectum of two series of animals a solution of sodium chloride mixed for one series with calcium, and for the other without calcium, and then examining the length of the column of phagocytes penetrating into the capillary tubes.

The difference between the two series was considerable. The calcium rabbits showed the greater degree of chemiotaxis, although the amount of calcium chloride used was very small—namely, 0.06 gram—a quantity corresponding with that given to man in mineral waters rich in calcium. Let us add that a natural mineral water, rich in calcium, used in our experiments gave the same results as the calcium chloride solution.

What can be said of the mechanism of this effect? The calcium, on being absorbed by the mucous membrane of the rectum, enters the blood circulation and by this is carried into the lymph of the tissue spaces, where the glass capillary tubes are placed. The phagocytes which are there will soon undergo the stimulating influence of the calcium thus introduced—that is, their mobility will be increased and chemiotaxis will be promoted.

Even without measuring the length of the phagocyte columns, we may convince ourselves that our conclusion as to calcium promoting the activity of the phagocytes is a correct one. On opening the skin wound it is immediately seen that in the mineral water rabbits a much thicker mass of phagocytes is gathered round the tubes than in the pure sodium chloride rabbits. The same thing we observed invariably in all experiments in which NaCl solution containing calcium chloride was injected.

Taking it for granted that phagocytosis plays a part in the defence against microbes, we may infer from the above that an enrichment of our blood, and through this also of the lymph spaces, with small amounts of calcium, must have a favourable effect on local and other infections.

There are many experiences supporting this view. I will mention only two examples. In the first place, Sir Lauder Brunton has used with great success calcium chloride in pneumonia. Other clinicians have also met with success along the same lines; for instance, Crombie, who some years earlier, in the hospital of Calcutta, saw the mortality decrease from 38.6 to 5 per cent. He was inclined to attribute the influence of calcium to an action on the poison excreted by the pneumonia bacteria. But for this there is no evidence. Sir Lauder Brunton has recommended calcium for getting amelioration of the heart action. In recovery from pneumonia the amelioration of the heart action is of the greatest importance. So it was quite rational that the famous clinician and pharmacologist advised calcium for this purpose—in the first place, because it was pointed out by the work of Sydney Ringer that calcium is absolutely necessary for the heart function, and, on the other hand, Langendorff and Hueck had found that by the injection of calcium into the circulation of a cat the action of the heart was considerably strengthened.

Sometimes it happens that during surgical operations the heart beat is stopped by the inhalation of chloroform. The idea occurred to me that in this case calcium might be able to be of good service. Therefore I tried to improve the heart action by intravenous injection of calcium in animals which had purposely been given too much of the anæsthetic. I had no success, so I began to doubt whether calcium was really capable of stimulating even the normal heart. In a number of experiments I found that injection of calcium had no effect on the heart beat of a normal animal. Studying the original article of Langendorff with renewed attention, I saw that he had performed only one experiment. His great reputation had given his assertion general acceptance, and so it had become a fact in the literature. Obviously the amount of calcium in the normal blood serum provides already just the optimum quantity for the heart function.

Thus this favourable effect of calcium in pneumonia not being explained by the influence of calcium on the heart, we had to look for another reason. It was therefore most

natural to remember the stimulating action of calcium on phagocytes, which in pneumonia play such a preponderant part.

My second argument for the probability that calcium is of importance in infectious diseases is this: Labourers in limekilns do not get tuberculosis; in Holland these workmen cover any wound they receive with lime.

The significance of calcium has for some time past been occupying the special attention of biologists and pathologists in an increasing degree, and I shall speak of it further now, and of the cause of the promotion of the activity of the phagocytes in phagocytosis and chemiotaxis by calcium, only to make one remark. We might be inclined to attribute the increase of the plasticity to a modification in the aggregation of the colloid protoplasm particles as a consequence of the electric charge caused by the entering of a number of bivalent ions into the cells. This explanation, however, can scarcely be the correct one here, for experiment shows that other bivalent cations—namely, barium, strontium, and magnesium—do not augment the amoeboid motion—that is, of phagocytosis and chemiotaxis. It must be assumed, then, that the action of calcium in this case is based upon a hitherto unknown specific biochemical property of this metal.

2. Influence of Iodoform on Phagocytosis.

Every one knows that for the last thirty years iodoform has been successfully applied in the treatment of wounds and chronic inflammations. At first it was thought that this favourable effect was based upon an antiseptic action, but the idea was relinquished when it was found that lower organisms develop fully in a medium containing iodoform. Then other hypotheses were suggested, which need not be dwelt on. They were founded mainly on iodine being split off. None of these suggestions have proved satisfactory. For reasons unnecessary to state here, we have raised the question whether the favourable effect of iodoform on local infections may not be due to the stimulating effect of this substance on phagocytosis. To answer this question, iodoform solutions of different concentrations in a common salt solution of 0.9 per cent. were prepared and mixed with a thick suspension of white blood corpuscles. After having added carbon particles, the mixtures were left to themselves for half an hour in an incubator at 37° C., and then cooled down. Finally, microscopic preparations were made and examined to determine what percentage of the total numbers of white blood corpuscles had taken up carbon particles. The following table contains the results of one of the experiments:

Concentration of Iodoform Solutions in which the Effect on Phagocytosis is still Perceptible.

Fluids.	Percentage of Leucocytes having taken up Carbon.
NaCl 0.9 per cent. (common salt solution of 0.9 per cent.)	$\left(\begin{array}{l} \frac{171}{388} \times 100 = 44.0 \\ \frac{151}{345} \times 100 = 43.7 \end{array} \right) 43.8\%$
1 iodoform to 100,000 NaCl 0.9 per cent.	$\left(\begin{array}{l} \frac{221}{274} \times 100 = 58.6 \\ \frac{226}{277} \times 100 = 59.9 \end{array} \right) 58.2\%$
1 iodoform to 500,000 NaCl 0.9 per cent.	$\left(\frac{228}{371} \times 100 = 61.4 \right) 61.4\%$
1 iodoform to 2,000,000 NaCl 0.9 per cent.	$\left(\begin{array}{l} \frac{208}{398} \times 100 = 52.2 \\ \frac{231}{445} \times 100 = 51.9 \end{array} \right) 52.0\%$
1 iodoform to 5,000,000 NaCl 0.9 per cent.	$\left(\begin{array}{l} \frac{232}{621} \times 100 = 46.9 \\ \frac{176}{372} \times 100 = 47.3 \end{array} \right) 47.0\%$

This table shows that, in the pure salt solution, of the 388 examined leucocytes 171 have taken up carbon—that is, 44 per cent. In a parallel experiment the percentage was 43.7 per cent. Thus the average was 43.8 per cent. In the salt solution containing iodoform in a proportion 1 grain to 100,000 grains NaCl solution, the percentage in two parallel experiments was 58.6 and 59.9, average 59.2 per cent. Evidently the iodoform promoted phagocytosis.

These and other parallel experiments illustrate also the exactitude of the method. As a matter of course, control

experiments have been made in all cases. Further, it appears that a weaker solution of iodoform (1 in 500,000) yields a still higher phagocytosis (61.4 per cent.). The explanation of this phenomenon will afterwards be given. It is seen that in still weaker concentrations the phagocytosis is diminished, but even in a solution of 1 iodoform to 5,000,000 salt solution, the promoting effect of iodoform is still perceptible, for it is 47.1 per cent., whereas in a pure NaCl solution it was $\frac{1}{2}$ ($44 + 43.7$) = 43.9 per cent.

The favouring effect of iodoform is still more evident when the leucocytes are placed for several hours in a pure NaCl solution. Then the phagocytosis falls to a considerable extent. Sometimes the phagocytes are quite paralysed. The addition of iodoform in a concentration of 1 in 5,000,000 then raises the phagocytic power by 30 per cent. or more. Thus there is no doubt that iodoform promotes phagocytosis.

Is it the iodine or the iodoform as such? We have found that iodine is noxious in a high degree. We must conclude, therefore, that iodoform as such causes the increase of the phagocytic power.

The question now suggests itself: How can the favourable effect of the iodoform be explained? It may be accepted from numerous investigations that the outer layer of the cells consists of a fatty substance, a so-called lipid surface. Now, iodoform is soluble in fat, and it is quite obvious that such a surface will grow more soft and more flexible after having absorbed iodoform, and that consequently the plasticity and mobility will be facilitated.

If this interpretation be correct, then other substances soluble in fat, such as chloroform, chloral, alcohol, benzene, camphor, fatty acids (propionic and butyric), should affect phagocytosis in a similar way. This is found to be invariably the case.

3. Effect of Chloroform, Alcohol, Camphor, Benzene, and other Substances Soluble in Fat on Phagocytosis.

I shall not give an account of all our experiments made in this direction. I only give as an example an experiment with chloroform, from which one can at once get an idea as to the exactitude of the method. It was soon found that dilutions 1 in 2,000, 1 in 6,000, and also 1 in 10,000 paralysed the phagocytes. The following table contains some experiments with weaker solutions:

Effect of Chloroform on Phagocytosis.

Fluids.	Percentage of Leucocytes having taken up Carbon.
NaCl 0.9 per cent.	$\left. \begin{array}{l} \frac{174}{428} \times 100 = 40.6 \\ \frac{208}{502} \times 100 = 41.2 \end{array} \right\} 40.9\%$
Chloroform 1 in 20,000	$\left. \begin{array}{l} \frac{244}{486} \times 100 = 50.8 \\ \frac{225}{451} \times 100 = 49.8 \end{array} \right\} 50.3\%$
Chloroform 1 in 100,000	$\left. \begin{array}{l} \frac{254}{519} \times 100 = 60.6 \\ \frac{382}{455} \times 100 = 60.1 \end{array} \right\} 60.3\%$
Chloroform 1 in 500,000	$\left. \begin{array}{l} \frac{332}{582} \times 100 = 57.0 \\ \frac{219}{376} \times 100 = 53.1 \end{array} \right\} 58.0\%$
Chloroform 1 in 5,000,000	$\left. \begin{array}{l} \frac{379}{805} \times 100 = 43.6 \\ \frac{298}{681} \times 100 = 45.0 \end{array} \right\} 44.3\%$

From this table it appears that chloroform 1 in 20,000 raises the phagocytosis power from 40.9 per cent. to 50.3 per cent.; further, that phagocytosis is considerably increased by chloroform 1 in 100,000, in which case it rises to 60.5 per cent. Evidently in the chloroform solution 1 in 20,000 the paralyzing influence also makes itself felt. In a dilution of 1 in 500,000 the favourable effect remains to about the same extent as in 1 in 100,000, and finally in a solution of 1 chloroform to 5,000,000 NaCl solution this favourable effect is still visible, though slight.

Similar results were obtained with benzene, camphor, turpentine, alcohol, chloral, fatty acids (propionic and butyric), and also Peruvian balsam. These all, without exception, promoted phagocytosis. Hence our hypothesis for explaining the effect of iodoform was fully confirmed. Another strong support to our hypothesis was obtained by

comparing the concentrations of the named substances which were able to increase phagocytosis. It appeared that the relation between these concentrations corresponded with that existing between the solubility of these substances in fat.

Further, all the substances applied in very small doses showed a stimulating effect, but paralysed when given in greater quantities. This can be explained by distinguishing two factors: First, slight quantities of the substance by dissolving in the outer layer of the cell weaken it and increase the plasticity. Then, greater quantities having entered the cell, a second factor, the paralyzing effect on the protoplasm, comes into play. As the amount of chloroform is increased the paralyzing effect gets the upper hand, and no carbon at all is taken up.

4. Other Phenomena seen in the Light of the Foregoing Facts.

The effect of fat-dissolving substances on phagocytosis throws a new light on several facts which hitherto have been, for the most part, entirely unexplained. In the first place we may refer to the power of turpentine to cause local exudations, and the favourable effect of a subcutaneous injection of the same substance in the treatment of pneumonia in horses and in the mastitis of cows, which for some time has been practised with great success in France, Denmark, and Holland. Experiments made by us in this direction have shown that there is much reason to attribute this effect to very small quantities of turpentine dissolving in the lymph of tissue spaces, and afterwards entering the blood circulation and promoting the phagocytic power of the phagocytes in lung and udder.

In the same way we can explain the marked effect of camphor treatment in inflammatory processes of the uterus and its adnexa, an effect not understood hitherto. Then there is the great effect of covering wounds with balsam of Peru, the therapeutic value of inhalation of turpentine vapour in tuberculosis and other infectious processes in the respiratory organs.

In all these cases a stimulating action on the phagocytes, and probably also on other cells (granulation cells), which play a part in the healing process, may come into play.

Yet more becomes clear to us from the above researches. It is well known that various narcotics applied in small doses have a stimulating effect and paralyse in greater quantities. Engelmann observed this many years ago on ciliated cells, but he did not try to explain it. Also, as regards the nervous system, we know with regard to chloroform and ether that, when administered, they first cause excitement and afterwards insensibility. So far as we know, this contrast has never been explained, but when viewed in connexion with our experiments, the phenomenon becomes clear. In the beginning of narcosis only small quantities have entered into the nerve cells. The consequence is a softening, in the first place, of the outer layer. This weakened state of the cells produces an increase of activity (amoeboid motion?). Later, when a greater amount of the substance has been taken in, the paralyzing effect gets the upper hand. With alcohol the same experience is well known.

In following this point we are led to think of the remarkable influence of a sojourn in some high mountain regions on metabolism, on sleep, and on the state of the mind. The cause is entirely unknown. It has been proved that these phenomena are not due to the height as such, for in balloons they do not occur, nor are they found in all high mountain regions, but when examining where they are observed, we find that it is in the neighbourhood of coniferous woods. So we are inclined to think that it is due to the stimulating effect of the odour of resin (turpentine, etc.) on the nerve cells.

Professor Sherrington and Miss Sowton, in their studies on the dosage of the mammalian heart by chloroform, found that, especially with greater amounts of the drug, it was usual for the first effect of the administration to be a distinct though slight increase in amplitude of the contractions. After cessation of the administration of the drug in moderate dose, it was not unusual, before the recovery, for the beat of the heart to pass over for a short time into a condition of super-activity. These phenomena suggest an irritative excitatory effect of small doses of the substance on muscle or nerve fibres (or both) of the heart.

These results agree with those previously obtained by Professor A. D. Waller in his experiments with isolated nerve.

There are experiments, also, with other organs which may be considered in the same light. Thus, Professor J. Loeb discovered that substances dissolving fat have the power of rendering possible the parthenogenetic development of eggs. Now we may imagine, with Loeb, that the substance dissolves in a lipid of the outer layer of the egg, thus giving rise to the formation of a fertilizing membrane. We think we may safely go one step further, and assume that it is owing to the weakening of the membrane that the movement of the protoplasm underlying every cell division manifests itself. This view is confirmed by the observation of Professor R. S. Lillie, who saw also that by a short transitory raising of the temperature in the eggs of starfishes a typical fertilizing membrane may be formed, which formation is followed by the development of part of the eggs into larvae. J. Loeb was able to confirm this for *Medusae*.

After consideration of the foregoing facts and suggestions we were inclined to think that the stimulating effect of traces of substances which dissolve fat on the activity of cells is a widespread phenomenon. Hence we have investigated whether this influence might also be seen in *plant cells*. To do so we chose the germination of seeds, a process in which a considerable division and growth of cells manifests itself. The seeds we chose were grains of wheat, and for the fat-solvent we took chloroform. With chloroform, 1 part in 100,000, an important acceleration in the germination was observed; chloroform 1 in 1,000, on the contrary, impaired the germination, evidently because a second factor made itself felt—namely, paralysis of the protoplasm. Later I heard that in practice the growth of snowdrops is promoted by ether. In recent times Chiari succeeded in forcing blossoms to a considerable extent by ether vapour, and Mansfeld the germination of pumpkin seeds by vapour of alcohol and ether.

Hence it is clear that the observations on phagocytosis deserve our attention on general grounds as well as special. We do not at all mean to say that all substances dissolving fat have the same effect on cells of all kinds; far from it. I would emphasize that in order to be brief and to avoid complexity of detail, I have here presented the matter as somewhat simpler than it really is. Nor have all the suggestions here made towards explaining facts regarding other cells than phagocytes been actually proved. Without hypothesis science cannot progress. Fortunately we need not stay in error for long, for we can always appeal to the supreme judge—experiment.

5. Effect of Oxygen and Carbonic Acid on Phagocytosis. Resemblance between Phagocytes and Respiratory Centre.

In continuing these researches we asked ourselves, for a reason we shall not dwell upon here, to what extent phagocytosis depends on the oxygen percentage of the medium.

For these investigations no carbon was used, because, as we know, this substance possesses the property of absorbing gases to a considerable extent. Instead of it we made use of rice-flour. The principle for determining the degree of phagocytosis was the same as for the taking up of carbon. It was determined what percentage of the leucocytes counted had taken up starch grains after a certain time.

By this method we compared the degree of phagocytosis in a common salt solution, treated with air, with oxygen and with nitrogen. The result of these experiments was quite unexpected; it appeared that the phagocytosis is greatest where the slightest amount of oxygen was present.

Repeated repetition of the experiment when only the NaCl solutions were compared which were not treated at all and treated with nitrogen, yielded similar results.

Effect of Treatment with Nitrogen on Phagocytosis. Degree of Phagocytosis.

The fluid not treated :	The fluid treated with nitrogen :
22.9 per cent.	26.1 per cent.
23.8 "	33.0 "
23.2 "	27.8 "
20.5 "	31.2 "

It is obvious that the treatment with nitrogen has caused an increase of phagocytosis.

However, the possibility remained that the nitrogen used contained substances which had accelerated the phagocytosis. This was not very probable, since the nitrogen supplied by the company "Oxygenium" at Schiedam had been prepared by fractionated distillation of liquid air. It still contains 1 per cent. of oxygen and gases of the helium group. At any rate, it seemed desirable to carry out experiments with hydrogen likewise. These experiments all resulted invariably in phagocytosis being promoted by the action of hydrogen. Hence it may be concluded that expulsion of oxygen from the medium causes an increase of phagocytosis.

However, the expulsion of oxygen from the cells in the foregoing experiments could not have been extensive, for their contact with the fluid from which the oxygen previously was removed had lasted only half an hour. So we repeated the experiments, with this difference, that the fluid treated with nitrogen and hydrogen could act for five hours instead of half an hour on the phagocytes. In this way the cells had every opportunity to consume the greatest part of their own oxygen. The results were striking; instead of an increase always a decrease of phagocytosis occurred.*

If we submit the results obtained to a close examination we are struck by the agreement between the effect which withdrawal of oxygen has on the respiratory centre on the one hand and on the phagocytes on the other.

After the many researches on the respiratory centre we may take it for granted that besides the action of CO₂ the respiratory centre is also stimulated by a withdrawal of oxygen. The respiratory centre increases its activity when oxygen is very scarce (dyspnoea) and is paralysed when O₂ continues to be withdrawn (suffocation, asphyxia); whereas by frequent deep respiration, by which the O₂ percentage of the blood is increased, the activity of the respiratory centre is lowered in such a degree that the respiration may be stopped for some time without the animal showing any need of it (apnoea).

In view of the agreement between phagocytes and respiratory centre, the question suggests itself whether other substances have likewise the same effect on both.

Therefore we have in the first place investigated the effect of CO₂ on phagocytosis. The experiments plainly demonstrated that in weak concentrations (for instance, 3½ volumes per cent. of CO₂ and less) carbonic acid increases the phagocytosis, and that in higher concentrations (for instance, 10 per cent.) it has a paralysing effect.

Involuntarily we are inclined to think here of the favourable effect of the therapeutic application of venous congestion in inflammatory processes of microbial nature (Bier). Probably the increasing of the amount of CO₂ accelerates phagocytosis. It is well known that a too energetic use of artificial venous congestion has an unfavourable effect on the inflammatory process, probably because the cells are paralysed.

Another substance having a highly stimulating effect on the respiratory centre before paralysis sets in is, as we know, potassium cyanide; a violent dyspnoea manifests itself. We found that KCN has the same effect on phagocytes—stimulating in slight doses, paralysing in somewhat greater quantities.

Now, it is all but certain that these phenomena must be connected with the property this substance has of obstructing the oxygen consumption of the cells.

6. Explanation of the Excitement Stage in Chloroform Narcosis.

As we have seen under heading 2, there is much evidence to justify the assumption that the stimulating effect of iodoform, chloroform, turpentine, and other fat-dissolving substances on phagocytosis must be connected with a softening of the outer layer of the cells. The present researches on the influence of O₂ withdrawal suggest the existence of a second factor.

The numerous researches of Verworn and his pupils on narcosis have established the fact that narcotics such as chloroform have the property of impeding the O₂ consumption by the cells (spinal centres, nerve fibres, amoebae, etc.). Now, it is obvious that as long as mere traces of

* We shall not give figures here; we only refer to the article in the *Proceedings of the Royal Society of the Netherlands* meeting of Friday, April 23rd, 1915, p. 1325, and also to more extensive articles on the subject which will appear in the *Internationale Zeitschrift für physikalisch-chemische Biologie*, vol. II.

chloroform are acting, only part of the available oxygen will be rendered useless; in other terms, the blockade of the oxygen will be incomplete, and then the phagocytes are in the case of the experiments mentioned under 5, where partial removal of oxygen by nitrogen or hydrogen causes an acceleration of the phagocytosis. This acceleration gradually passes into a retardation in proportion as the store of oxygen of the cell becomes more exhausted—an exhaustion which sets in quickly when, for instance, by the administration of larger amounts of chloroform, the oxygen consumption has fallen to a minimum or has ceased altogether.

The Excitement Stage in Chloroform Narcosis.

If we let the various narcosis theories pass in review, it appears that no one has even attempted to give an explanation of the excitement stage.

In his article "Narkose"¹ Verworn says: Für die Genese des Exzitationsstadiums fehlt bisher jede Analyse.

Our researches on phagocytosis and the agreement in the conduct of the respiratory centre and phagocytes may be useful to lighten the difficulty.

We need only to conceive that in the beginning of the narcosis, owing to a decrease in the amount of available oxygen, the sensibility of the higher nerve centres is heightened.

If the chloroform inhalation is continued, this sensibility will decrease, owing to a further decrease of the potential oxygen percentage, and finally narcosis sets in. Whether the state of complete narcosis is partly due to other factors—for instance, to a semi-coagulation of the protoplasm in the sense of Claude Bernard, or to a decrease of the dispersity of enzymes, etc.—need not be considered here. First, the higher centres, which are, as we know, very sensitive to oxygen withdrawal, are paralysed; then the spinal centres; and, after that, the respiratory centres.

We may add that in the first stage of narcosis not only the higher cortical centres and the spinal centres pass through an excitement stage; but, according to researches of Knoll and of Arloing, the respiratory centre is also in a state of heightened irritability.

Probably the increased sensitiveness as a result of a partial oxygen withdrawal must be looked upon as a general phenomenon. The sensitiveness of the vomiting centre, for instance, decreases, just like that of the respiratory centre and phagocytes, if more oxygen is supplied. Hence the inclination to vomit may be subdued to some extent by frequent and deep breathing, whilst it is stimulated by lack of oxygen.

The question which first suggests itself is the following: How is it that a decrease of the available oxygen percentage heightens the irritability of the phagocytes (and ganglion cells)?

The foregoing accounts of results and views, the fruit of some years' work with several collaborators (Hekma, De Haan, etc.),² being of necessity incomplete, I have attempted to select what may specially interest every medical man.

We are continuing our study of the biology of phagocytes, and each day we become more convinced of their excellence as a simple object for the study of problems of a general biochemical nature, and of some of practical interest as well.

It is a satisfaction to me that other workers have begun to cultivate this field of research and to follow our method of investigation.

MR. CLEMENT LUCAS left property of the value of £33,487, the net personalty being £20,976.

At a meeting of the K.k. Gesellschaft der Aerzte in Vienna, Dr. A. v. Hauer, in giving an account of eight months' experience in the field, discussed the subject of self-mutilation; soldiers with wounds of the left hand were, he said, at once interrogated with this possibility in view. Inoculation against cholera was repeated every three months; active immunization against typhoid fever and small-pox was also undertaken.

An Address

ON THE

ABSENCE OF PROPER FACILITIES FOR THE TREATMENT OF MENTAL DISORDERS IN THEIR EARLY STAGES.

DELIVERED AT A MEETING OF THE YORKSHIRE BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

BY

BEDFORD PIERCE, M.D., F.R.C.P. LOND.,

MEDICAL SUPERINTENDENT, THE RETREAT, YORK;
PRESIDENT OF THE BRANCH.

ONE hundred years ago, whilst the campaign in Belgium which ended at Waterloo was in progress, a Select Committee of the House of Commons was engaged in inquiring into the conditions of madhouses in England. Its report, presented in July, 1815, disclosed a terrible state of things, and did much to awaken the public conscience. Amongst those who gave evidence was William Tuke, the founder of the Retreat, then 83 years of age, and frequent reference is made to the *History of the Retreat*, published in 1812, which, largely owing to an article by Sidney Smith in the *Edinburgh Review*, entitled "Mad Quakers," had much influence in promoting improved treatment of the insane. Among the institutions reported upon were some spoken of in the highest terms, in particular Dr. Fox's house at Brislington near Bristol, and Dr. Finch's, Lavestock House, Salisbury, but in the main the state of affairs disclosed was horrible beyond description. One case investigated became notorious—namely, that of a man named Norris, who was restrained for fifteen years at Bethlem with a triple arrangement of bars and chains.

I do not wish, however, to discuss the abuses that existed at that time, and continued more or less for another thirty years, until the appointment of the Lunacy Commission finally put an end in this country to the era of straw and chains in the treatment of the insane.

My object in referring to the report of 1815 is to point out that, in spite of the grave condition of public affairs caused by Napoleon's escape from Elba and his success in raising an army of 250,000 men in less than three months, a committee of the English House of Commons week after week calmly listened to evidence dealing with the management of madhouses. The nation is again passing through a serious crisis in its history, but unless the British character during the past century has seriously altered, it will not be long before the country will be willing to give attention to social questions. To refer to a subject which involves the expenditure of public money at the present time would seem futile, yet it did not discourage our ancestors, exhausted and almost ruined by the Napoleonic wars. On the Friday before the battle of Waterloo the Select Committee considered designs for the construction of two asylums in London and Yorkshire respectively, estimated to cost together £36,596.

The lull of political controversy would seem to afford a singularly opportune time for considering whether any alteration in the law is required in the interests of persons threatened with mental disease. I therefore do not hesitate in bringing to your notice a subject which I believe to be of great importance—namely, the absence of proper facilities for treatment of nervous and mental disorders in their early stages. Its importance was long ago realized by the British Medical Association, which, with the Medico-Psychological Association and the Medico-Legal Society, repeatedly advocated a change in the law. Immediately before the outbreak of the war the Medico-Psychological Association adopted the report of a special committee advocating the establishment of clinics for the treatment of early cases. In the medical press recently the subject has again been discussed, and general public attention was called to the matter, when it was realized that, apart from certification, there was no legal method of treating soldiers temporarily disordered in mind. It was at once seen that the existing procedure was impossible for men temporarily broken down in the service of their country, yet a bill introduced into Parliament to meet the case failed to pass. Although the difficulty in respect to soldiers has to a large

extent been overcome, I would urge the British Medical Association to consider afresh whether some radical change in our procedure cannot be secured, so that all on the verge of mental collapse, as well as those whose breakdown is recent and may be considered temporary, can receive effective treatment in a properly equipped hospital without the necessity for certificates of insanity.

Let me state in a few words the defects of our present system. At present, broadly speaking, no person unable to pay its cost can receive adequate treatment until he is certified as of unsound mind. This practically means that no special treatment is possible until he has utterly broken down and is so seriously affected as to convince a magistrate that he is decidedly insane. No general hospital will receive such a patient; the public asylums are all closed to any one who begs for protection or treatment, for county asylums cannot receive voluntary boarders even when the cost of their maintenance is forthcoming.

Consequently there is no alternative but to apply to the Poor Law authorities, who, under certain circumstances, provide treatment for a period of two weeks in the workhouse infirmary. The whole system is radically wrong. When the wife of an artisan becomes depressed after confinement, surely it is cruel in the extreme to make her a pauper and send her to the workhouse infirmary, pending a decision as to whether she is insane or no. It is obvious in such a case that this course will not be adopted until the last possible moment, and consequently much valuable time is lost.

Every practitioner will be able to call to mind patients travelling steadily towards insanity in unfavourable surroundings. This question is brought even more prominently before consulting physicians, especially those interested in nervous and mental diseases.

Dr. Henry Maudsley's generous gift of £30,000 to the London County Council to establish a hospital for recent and undeveloped cases shows most plainly how the matter appears to one of the foremost thinkers of the day and a physician who has spent his life in the study of mental disorders. Dr. Maudsley's books are already classics, they are quoted, consciously or unconsciously, by all who have written on the subject of insanity in recent years, and it was a noble act on his part to assist in meeting the crying need of those threatened with or struggling against mental infirmity. As I write the hospital is nearly ready, but owing to the exigencies of the war it is, for the present, I understand, to be used exclusively for soldiers.

If it were possible, instead of a separate hospital it might have been better to establish separate pavilions for nervous and mental diseases in direct association with general hospitals. At La Charité hospital in Berlin the visitor enters a small park, and Dr. Zichen's clinic is but one of many detached buildings devoted to special diseases. It is as easy and simple for the patient suffering in mind to get advice there as for another with eye or with lung trouble. In most cities in England, however, any such arrangement is impossible, for general hospitals cannot be rebuilt or reconstituted in this way.

In order to give some idea of the extremely valuable work done at special hospitals of the kind advocated, I will briefly allude to the Psychopathic Hospital at Boston, Massachusetts. I have before me the notes of the first and the second annual conferences of the medical and social work at this hospital.¹ The hospital was built by the State expressly to deal with recent acute cases. No fewer than 1,523 patients were received in its first year, and of these 590 were received under a temporary care law which provides for a week's detention only; large numbers were also received on a voluntary basis, so that during the year 48 per cent. of all patients escaped the usual lunacy procedure.

On reading the reports of work done, one is struck with the enthusiasm of the medical staff and the vast field of research undertaken. During the two years eighteen medical men describe their work covering almost every department of psychiatry: Juvenile crime, tests for feeble-mindedness, incidence of syphilis, alcoholism, hydropathy in its influence on red blood cells, treatment of delirium, prophylaxis, analysis of genetic factors, salvarsan treatment, tests of cerebro-spinal fluid, errors in diagnosis, and last, but not least, the value of out-patients' departments and after-care. There is a special social service department for the purpose of following up cases in their homes,

and it was found that of every 100 admissions 20 needed supervision on discharge, 24 needed advice, 3 required assistance in arranging their discharge, and 10 showed a need for prophylactic work in their families.

This bald statement of the activities of the Boston State Hospital shows plainly what an important service it renders in providing treatment apart from ordinary asylum associations. It shows how it is possible at such a hospital to organize a medical service which covers all departments of psychiatry; and, further, that when the mental symptoms clear up, a patient need not be thrown back into old associations without help or supervision.

This hospital at Boston is but one of many that have been established in the United States in recent years. Some of the others are due to private munificence; in particular, reference may be made to the Henry Phipps Psychiatric Clinic at Baltimore, the medical staff of which consists of a director, assistant director, a resident physician, two assistants, and five internes. In addition to these are the heads of three research laboratories, dealing (1) with clinical pathology and bio-chemical investigation, (2) with neurological research, and (3) with psycho-pathology.

It would give a wrong impression to conclude that nothing whatever has been done in this country, seeing that the city of Glasgow has provided excellent hospital accommodation for the temporary care of doubtful and recent cases in association with the Poor Law infirmaries; and in London, Liverpool, and elsewhere the hospitals under the control of the guardians are well equipped and very efficient institutions. I think, however, that I am justified in stating that even in these localities the facilities fall far short of what is really needed, whilst the medical staff is relatively very small. Besides this the association with the Poor Law is a serious drawback. In the words of the report of the Medico-Psychological Association:

The present system, which compels all persons, except those able to pay adequately for their maintenance, to apply to the Poor Law authorities in order to secure treatment, is unsatisfactory and unjust. In doubtful and undeveloped cases temporary care can be given only in workhouses or Poor Law infirmaries, which, with very few exceptions, lack proper facilities for treatment.

A system which artificially creates paupers in order to obtain medical treatment necessarily acts as a deterrent, so that too frequently there is serious and even disastrous delay.

There is, however, one hospital specially devoted to the care of mental and nervous diseases free from these objections, though I fear the small financial support it receives greatly limits its usefulness. This pioneer institution is the Lady Chichester Hospital, Hove, Brighton, for cases of nervous breakdown, established chiefly through the efforts of Dr. Helen Boyle. In a small way it represents the ideal, as it is affiliated with a hospital for medical and surgical cases, and it is free from Poor Law associations. From the annual report I extract the following, referring to the patients admitted:

Many such are entirely dependent upon their own exertions, and the knowledge that no refuge existed for them would render them a more easy prey to disease. Others are wives and mothers of families whose circumstances make it impossible for them to get rest or relief so long as they remain in their own homes. The only chance is to take them away from the daily strain and constant succession of unavoidable worries. Failing this they may only too easily cross the narrow line which divides the borderline case from that which is actually certifiable as mental. At present this is the only hospital in the United Kingdom which deals with such cases of early nervous breakdown in poor people; it has therefore the strongest claim possible to the support of those who realize the danger and the expense to the community entailed by failure to give help soon enough. It is needless to say that the 33 beds provided in this hospital are wholly insufficient to meet the demands, patients having to wait months for admission sometimes, and it cannot be too often repeated that treatment of this kind is one of the most pressing requirements of the present time.

The value of special hospitals for nervous and mental disorders has been demonstrated in a remarkable manner by the conversion of the State Hospital, recently equipped by the Board of Control under the superintendence of Dr. Rees Thomas, into a Red Cross hospital for soldiers suffering from shock and other psychoses. It is singularly fitting that the organization and management of this hospital since Dr. Thomas left for active service should fall upon Dr., now Major, Rows, who perhaps more than

any other person has laboured for the establishment of clinics and special hospitals of this kind.

The Moss Side Hospital, Maghull, accommodates some 280 patients housed in six pavilions. They suffer from all kinds of nervous maladies arising in the course of active service. Two-thirds of the patients are nursed entirely by women nurses. As the patients are soldiers, and have been drafted from Netley in the ordinary way, no difficulties arise as to legal status.

It is satisfactory to find that the medical staff is relatively strong, exceeding that of almost any similar institution. For the 280 patients there are seven whole-time medical officers, most of whom are men with great experience in this department of medicine. This is not the place to refer to the enthusiastic work of these gentlemen; no doubt in due course reports will be published. Yet I may be permitted to say that a recent visit to this hospital yielded me great satisfaction in two directions. First, that our soldiers shaken or disturbed in mind in the course of their duty are receiving the best and most skilful treatment that modern psychiatry can provide; and secondly, that a hospital already is in being which illustrates what might and should be done throughout the country for those threatened with mental failure and on the verge of insanity.

When we consider the problem of securing effective treatment for those in a position to pay for it the difficulties are not greatly reduced. No doubt patients whose conduct is not disorderly and who are not actively dangerous to themselves and others can obtain treatment in a number of different ways. Nursing homes, private lodgings, doctors' houses, special arrangements in their own homes, hydropathics, are open to them, as well as foreign travel and health resorts of all kinds. All these are of value in certain cases, but it will be generally admitted that there is a large residuum of cases which cannot be nursed to the best advantage outside a special hospital. Under the existing state of the law only institutions available are the recognized institutions for the insane, and these are not considered until almost everything else has been tried. It is consequently not far wrong to assert that the richer the patient the less likely is treatment in a special hospital to be adopted early in the course of the malady. Two deeply rooted prejudices cannot be ignored. There is, firstly, the dread of asylums and of any association with the insane, and, secondly, the objection to certificates. It is useless to say that these prejudices are due to ignorance, and need not be seriously considered, for they are strongly entrenched in all grades of society, medical practitioners and others with personal knowledge of the subject not exempted. This dread does not seem to arise merely from the thought that insanity brings a stigma upon a family through the disclosure of hereditary weakness, although no doubt the incidence of insanity is feared from this point of view. Nor do I think that it is due to an idea that mental disorder is specially terrible owing to the possibility that the higher and nobler qualities of mankind may be lost. I have met persons otherwise level-headed who cannot be persuaded to enter the grounds of an asylum. Not infrequently all sorts of excuses are made to escape the duty of visiting a relative who is under care, and so real is the danger of neglect that the State has decreed that no order for reception shall be granted without an undertaking that the patient shall be visited at least every six months.

It seems clear to me that these prejudices are independent of any reasoned explanation and are due to traditional beliefs. That our lives are greatly influenced by these is not open to doubt. Superstitious notions are implanted in our minds from our earliest years. Old wives' tales are repeated by servants and casual visitors, and are eagerly listened to by the young, and it takes many years to destroy their influence, and, indeed, in many of us beliefs so acquired form a permanent part of our mental furniture. The origin of many such notions may be lost entirely, but I think in the present case these prejudices about insanity are directly descended from mediæval beliefs about evil spirits and demoniacal possession. The thought that madness is due to a possession is, moreover, strengthened by the way in which Scripture is taught. "He hath a devil and is mad" indicates plainly the current view of insanity at the beginning of the Christian era, which view exists to this

day in the East and has certainly not died out in our own country. I would therefore suggest that the unreasoning prejudice against the insane, the supposed stigma that attaches to insanity, really at bottom depends upon a survival of the superstition that mental disease is due to evil spirits. In other words, there is thought to be something uncanny, mysterious, and supernatural about disorders of the mind, and this gives rise to unreasoning dread of any association with insane persons.

I know of no remedy for these erroneous and cruel views but the gradual enlightenment of the public. I incline to think our asylums and hospitals are too much cut off from the world at large, and that too little is known of their patients and their doings.

Unfortunately the general practitioner is generally not in a position to assist in this enlightenment. Very few of them have lived in asylums, and the teaching of medical students is hardly calculated to give them much knowledge of the insane, though they may learn something of insanity. The situation is aggravated by asylum practice being divorced from general medicine to a large extent, and it is quite common for an experienced medical man to say without apology that he knows nothing whatever about lunacy. When the special hospitals already referred to are established we may confidently assume that they will become centres of education in all matters relating to insanity, and at the same time provide vastly better facilities for the instruction of medical students than exist at present.

Apart from the prejudices in relation to asylums, we must not forget that there is a widespread belief that association with other patients is itself injurious. No doubt there are some patients who do better in single care under domestic surroundings away from doctors and nurses and other patients, and it is quite true that in the best arranged institutions an observant and sensitive patient cannot but see much that is painful; nevertheless, I have never found any real hurt from this, and sometimes it is positively helpful to find that others are suffering in a similar way. Experience shows quite clearly that the association of patients is, broadly speaking, helpful rather than the reverse, so long as the size or the resources of the institution admit of satisfactory classification.

The other prejudice, the objection to certificates, is in many cases not without justification. I do not wish to defend those who resent certificates because they state an unpleasant and unwelcome truth, and who would close their eyes to the facts of the case. Such persons fail to see the immense value of the lunacy laws, and that to conceal the existence of insanity is to deprive persons unable to look after themselves of the protection of the King or the representatives of the Crown.

I therefore admit at once that persons who break down mentally cannot be treated in exactly the same way as those suffering from an ordinary ailment. Indeed, I am not sure that the law is strict enough in reference to established insanity, seeing that so many persons are treated privately without proper supervision. However this may be, it seems to be unjust in the extreme that persons with ill-defined or very temporary attacks of mental disorder should be unable to obtain effective treatment without being certified as of unsound mind.

Voluntary treatment can, it is true, be obtained in hospitals and licensed houses, and this is of the utmost value in many cases, and should be possible in all asylums. Yet experience shows that treatment on this basis is insufficient, for the reason that many patients most needing temporary care are unable to decide for themselves what treatment should be adopted.

Let me briefly illustrate the difficulties. Some years ago the managing director of a flourishing business was attacked by melancholia, and tried to throw himself out of a train. He was certified and sent to a hospital for the insane, but recovered in a week. On his discharge at the end of a month he found that another had been appointed to his post, and to this no exception could be taken, as the articles of association of his company contained the usual clause that a director who becomes insane is at once disqualified. Again, a medical man in large practice suddenly became seriously depressed with delusions of persecution. It was clear that special care was imperative, and he was certified and sent to a licensed house, where he recovered very quickly. In default of

any other procedure nothing else could have been done, and yet I could not but sympathize with his conviction that such a step ought to have been avoided.

Certificates are also objected to on account of the attendant disturbance of business affairs. A professional man holding several appointments suddenly lost his memory of recent events, although retaining his general intelligence. His affairs were managed by his son, who was his partner, to the satisfaction of every one. Unfortunately, as so frequently happens, the old gentleman became restless at night, and care in an institution was advised. He was quite willing to go away voluntarily, but owing to his defective memory he could hardly remain as a voluntary patient, not being able to remember his position. When certificates were proposed it transpired that they would mean a loss of £400 a year, as his appointments would have to be given up; and, moreover, the power of attorney given to his son would become invalid, so that his whole business affairs would be disorganized. In such a case in all probability a receiver would soon become necessary; yet it seems altogether wrong that such a man should at once be exposed to these disabilities when he breaks down mentally, seeing that he might be away from business for six months, and incapacitated in body and mind, by typhoid fever without any difficulties of this kind.

I have not forgotten a favourite legal maxim, "Hard cases make bad law"—an excuse for injustice which is not very convincing. But the difficulties I have mentioned are not exceptional. It is no exaggeration to say that in at least one quarter of the cases I see in consultation the impossibility of securing effective temporary care, apart from certificates, is a serious matter. One of my case-books contains 239 consecutive cases seen in consultation, and of these 79, or 33 per cent., needed the special care referred to. In a recent acute case it is obviously desirable that asylum care should not be hastily undertaken, and indeed it is only fair to the patient that it should be delayed until the real nature of the case can be made out, and yet at present for rich and poor alike there are no properly equipped homes or sanatoriums where treatment can be given temporarily under favourable conditions.

Directly we begin to consider the possibility of establishing any such hospital we are beset with difficulties. The hospital which I picture in my mind is affiliated to the general hospital of the district; it has a large garden, in which are several pavilions. There is both a resident and a non-resident medical staff, which collectively is able to attack mental disease from all sides. The patients would for the most part be received on a voluntary basis, though, if needful, detention for defined periods would be possible, whilst the equipment would include all appliances likely to assist in diagnosis and treatment.

Such public hospitals would usually, as in Boston and Munich, be municipal institutions, and in the long run they would prove to be a good investment of public money, owing to the large amount of insanity they would prevent.

The establishment of similar institutions for paying patients presents even greater difficulties, unless there is some change in the law. In existing circumstances there would be constant risk of prosecution under the 315th Section of the Lunacy Act, as it would be impossible to prevent patients stepping over the border, and the utility of such a home or sanatorium would be lost if such persons could not temporarily be detained. Hitherto proposals to enlarge existing powers of compulsory detention have been viewed with suspicion by a large section of the public, and several bills designed to meet these difficulties have been rejected by Parliament.

The legal profession views with grave concern any interference with the liberty of the subject, although a lawyer friend of mine, in discussing this matter in relation to the present state of public affairs, cynically remarked that "if there are any liberties left in England, now's the time to remove them."

This problem will not be solved until it is clearly recognized that there is no defined line between sanity and insanity, but rather a vague intermediate zone, and that those who enter this region urgently need the best possible treatment. I would therefore plead for legal recognition of this intermediate borderland state, and, as some power of detention in certain cases is required, safeguards must be provided that will disarm criticism.

The greatest of all safeguards is the absence of any concealment, and at once we find that in this matter public and private interests clash. It is only reasonable that families should not wish the state of an afflicted member to be generally known, and patients temporarily suffering from mania, or indeed any form of insanity, are entitled to privacy. Consequently the wards of the psychiatric hospital cannot be open to the public in quite the same way as those of a general hospital.

The suggestion has been made that the law should recognize a new class of patient suffering from undeveloped insanity, who under certain conditions might be detained for a stated period. How long this should be is a matter for discussion; probably a month in the first place would be sufficient, to be extended with the approval of the supervising authority for a further period of not more than five months. The names of all such patients would doubtless be notified to the Board of Control, and they might be styled "notified" patients, as distinct from voluntary boarders on the one hand and certified patients on the other.

Keeping in view the chief safeguard—absence of concealment—I would suggest that periodic reports of every case should be sent to the Board of Control, and that it should be obligatory to keep records for inspection by visiting members of the Board. I see no reason why the correspondence of "notified" patients should be interfered with. Further, no patient should be detained under this provision except in homes or institutions approved by the Board of Control.

All such approved homes should be inspected regularly by visitors nominated by the Board of Control, or possibly by county councils; if these visitors reported unfavourably in any individual case, the patient would have to be discharged or certified.

I see, moreover, no reason why notified patients should not be received in any recognized institution of the insane, or into special departments of such which the Board of Control might consider suitable for the purpose.

This amendment of the law would prevent evasion and the illegal detention of patients in lodgings or in private care that is now notorious. What has been termed the "back-parlour treatment" of the insane would be abandoned as far as recent incipient cases are concerned, and it is these that are of the most consequence. Special hospitals, such as the Maudsley Hospital, and psychiatric clinics generally, would be able to treat to recovery a large number of patients who must now be certified.

These two recommendations—the establishment of special hospitals or sanatoriums for the treatment of medical disorders in their early stages, and the modification of the law required to render such treatment effective—are, in my opinion, matters of the utmost importance. Not only will they do much to prevent declared insanity, but these special hospitals will become centres of enlightenment, and so disperse the unhappy prejudices and errors that surround the subject, whilst the larger clinics associated with universities will afford students opportunities of studying practical psychiatry which they do not now possess.

PERIPHERAL SHOCK AND ITS CENTRAL EFFECTS.

By J. LYNN THOMAS, C.B., F.R.C.S.,
SURGEON TO THE KING EDWARD VII HOSPITAL, CARDIFF.

THE admirable paper in the *BRITISH MEDICAL JOURNAL* of December 11th, 1915, by Dr. F. W. Mott, on "The psychic mechanism of the voice in relation to the emotions," reminds me of a remarkable case of deaf-mutism which came under my observation some years ago. This condition existed in a collier for about seven years, consequent upon receiving a "shock" in an underground colliery explosion. He was eventually cured by another shock during a second colliery explosion underground; he regretted that he never recovered the power of singing, as he had belonged to a choir before the first accident, and was incapable of rejoining it on that account, although he still enjoyed listening to music.

After his recovery this patient came to a surgical ward

at the Cardiff Infirmary, and it was through the accident of my going into the ward during visiting hours and seeing him converse with his wife in the deaf-and-dumb language that I obtained his singular history.

He was one of the few survivors in a big colliery explosion. He remembered nothing of the accident, but on recovering consciousness found that he could neither hear a sound nor articulate a word. After remaining in this condition for a considerable time he went to a school for the deaf and dumb, and eventually married a congenital deaf-mute. He lived happily in this state for some years, and resumed work until the occurrence of a second underground explosion, which was followed by his recovery from deaf-mutism; he stated that he distinctly remembered "hearing the ground tremble" before lapsing into unconsciousness which lasted a few days. When he regained consciousness he got very excited upon discovering that his powers of speech and hearing had returned. The late Dr. Naunton Davies, J.P., of Porth, told me that he knew the man well, and that in his opinion there was a strong hysterical strain in him; Dr. Davies said also that there was no evidence of direct injury to the head.

The present war has added to our knowledge of the causation of symptoms which are clinically so well known, and are described in the textbooks in chapters on concussion of the brain. It is no longer necessary to assume that "*commotio cerebri*" must have taken place, due either to a direct force—a "whack" or "crack" on the head—or to indirect force transmitted through the atlantoid articulations with the occiput producing a jarring of the skull and its contents. It can now be easily realized by those who have seen and studied the effect of high explosive shells upon the buildings of a town or village in the vicinity of which explosions have taken place. The damage which *atmospheric disturbances* alone can do to buildings, even at great distances from the site of the explosion, has strikingly illustrated the effect such air currents must have upon human beings, whether standing or lying down, awake or asleep. To me the damage done to buildings carries the conviction that the general shock to the whole surfaces of skin and mucous membrane which protect the exterior of man may be sufficient to disturb the nervous machinery to a degree which may vary from slight symptoms of concussion of the brain by stages which may reach the extremity of sudden death, without showing evidence of any appreciable naked-eye pathological signs.

I have had the opportunity of seeing the effect of air disturbances caused by colliery explosions, and these are in some aspects as powerful as those of "shell concussion." Further, I am of opinion that many of the freaks of lightning can be best explained upon the hypothesis that the tracks of lightning sparks cause sudden violent air currents, in the nature of vortices, ripples, or waves. These air blasts are often of a weirdly powerful intensity; the most striking example that has come under my own observation since I recorded—at the Oxford Meeting of the British Medical Association in 1902—the cases of two men struck by lightning, was one in which a key that had not been turned on the inside of a door was driven right across a room several feet high, marking by its impact the wall against which it struck; at the same time the beading on the exterior of one of the door-boards was stripped off and carried in an opposite direction to that taken by the key. I do not wish to weary the reader by quoting further illustrations of the effects of lightning air-currents in splitting dry wood or in blowing bark off dead trees. I want merely to emphasize the fact that in a large number of cases violent air-currents striking against skin and mucous membranes, whether originating in war by high explosives, or in civil life by colliery explosions, and by lightning, play *per se* the principal part in the etiological factors which cause disturbances of function in the psychic, physiological, and automatic centres situated in the brain itself through impulses conveyed to it. The special intermediate organs existing between the exterior of man and his brain, such as the eyes and ears, are frequently put out of gear by these air-currents or "shell concussion," and Mr. Jameson Evans, in the number of the BRITISH MEDICAL JOURNAL referred to above, gave some striking illustrations of such damage to vision. On the other hand, cases of severe labyrinthine trouble of the ears have been found to exist after patients recover from

the unconsciousness of severe concussion of the brain, as exemplified by the experiences of a young man who was "blown up" at Loos, and discovered that he could not direct himself to getting out of the side of the bed he wanted to, and that when he did get out he found himself staggering and reeling; these symptoms disappeared in two or three days, leaving in the course of a few weeks only partial deafness of one ear.

It will be noticed in the history of the case of deaf-mutism in a collier related above that he suffered from two types of shock—or symptoms of concussion of the brain—the first one occurring suddenly or instantaneously, that is, without consciousness of the accident on his part; whilst the second one had a latent period, that is, consciousness of the action before he lapsed into unconsciousness. I have observed the same two types of shock in cases of lightning stroke.

It is manifest that it is only in the type of "shell shock" in which a latent period occurs before the onset of the state of unconsciousness that the psychic centres can exert any influence upon the nervous machinery of the emotions.

The grim reality of the misnomer, "hysterical manifestations in a neurotic," is dramatically portrayed in the case related above, where the collier, upon recovering his power of speech and hearing, found himself married to a congenital deaf-mute!

OBSERVATIONS ON CASTELLANI'S "TETRAVACCINE" AND "PENTAVACCINE."

BY

G. A. LURIE, M.D. CHICAGO,

ATTACHED TO THE AMERICAN RED CROSS SANITARY COMMISSION IN SERBIA.

To Castellani is due the credit of having first proposed, prepared, and used, combined vaccines. The preparation of such vaccines is based on the experimental work he carried out in 1901-1902, when he was able to demonstrate that an animal (rabbit) inoculated with more than one species of bacteria, within limits, elaborated agglutinins and immune bodies for the various species injected, and that the amount of such protective substances for each species was not distinctly less than in control animals inoculated with one species only.

Castellani's best-known mixed vaccines are the tetravaccine "typhoid + paratyphoid A + paratyphoid B," which he began using in man on a large scale in 1905; the tetravaccine "typhoid + paratyphoid A + paratyphoid B + cholera"; the tetravaccine "typhoid + paratyphoid A + paratyphoid B + Malta fever"; the pentavaccine "typhoid + paratyphoid A + paratyphoid B + cholera + plague."

It may be of interest to put on record the experience I have had in Serbia of two of Castellani's vaccines—namely, the tetravaccine, typhoid + paratyphoid A + paratyphoid B + cholera; and the pentavaccine typhoid + paratyphoid A + paratyphoid B + cholera + Malta fever.

The two vaccines were obtained from Dr. Castellani, who was preparing them in Serbia on a large scale for the American Red Cross Sanitary Commission and for the Serbian army. The details of technique for the preparation of such vaccines may be found in his own publications; I limit myself to stating the results I have had.

Tetravaccine.

The tetravaccine was used by me to inoculate 3,000 persons, most of whom I was able to follow for two months after inoculation. Two injections only were given ($\frac{1}{2}$ c.cm. each) at an interval of five to seven days. The injection was done subcutaneously in the arm, after sterilizing the skin by means of tincture of iodine. The local reaction was generally mild, a few hours after injection a small patch of redness developing, with slight pain, which lasted one to two days. The general reaction was also, as a rule, mild. All the inoculated persons were able to attend to their duties twenty-four to forty-eight hours after the injection. I was able to keep in touch for two months with 2,000 of the inoculated persons; no case of typhoid, paratyphoid A, paratyphoid B, or cholera developed among them. With the kind assistance of Dr. Castellani, I

examined the blood of four of the inoculated persons. I have collected the results in the following table:

Tetravaccine.		Limits of Agglutination. Weeks after First Injection.				
Individuals Inoculated.	Blood tested against	1	2	3	4	5
No. 1.	<i>B. typhosus</i> ...	1/40	1/1200	1/500	—	1/200

Comparing the results collected in the above table with the results obtained in control individuals inoculated with monovaccines by Dr. Castellani and Dr. Mendelson, I find that the amount of agglutinins present is not distinctly smaller.

Pentavaccine.

The pentavaccine I used was the typhoid + paratyphoid A + paratyphoid B + cholera + Malta fever. I obtained it from Dr. Castellani. As regards the technical preparation of this vaccine I refer the reader to Dr. Castellani's own publications. I inoculated with this vaccine 2,000 individuals, mostly at the inoculating department attached to the Uskub American Clinic, with no untoward accident of any kind. The injections were given ($\frac{1}{2}$ c.cm. each) at an interval of five to eight days, with the usual technique. The reaction, local and general, was not more severe than in individuals inoculated with the tetravaccine. The blood of two of the inoculated persons was examined with the kind assistance of Mr. D. de Silva.

The results are given in the following table.

Pentavaccine.

	<i>M. melitensis</i> ...	1/10	1/40	1/200	1/150	1/80

CONCLUSIONS.

The use of Castellani's tetravaccine, typhoid + paratyphoid A + paratyphoid B + cholera, is harmless, and the inoculated persons develop protective substances for the four diseases. My results are therefore identical to those obtained by Castellani, Mendelson, and Randon, who have used that vaccine on a very large scale.

The use of the pentavaccine, typhoid + paratyphoid A + paratyphoid B + cholera + Malta fever, is also harmless, and, according to my experiments, the inoculated persons develop protective bodies for the five diseases. In my opinion, these mixed vaccines should be used as a matter of routine in all countries where such diseases exist already or may be easily imported.

REPORT OF A CASE OF SEVERE TETANUS SUCCESSFULLY TREATED BY ANTITOXIN.

BY

T. P. KILNER, CAPTAIN R.A.M.C.(T.F.).

THOUGH the following report was written in the earlier months of the war, when tetanus was much more commonly seen than it is now, it still may be justified in its publication in that it may give some little guidance to those who are called upon to treat the cases of a similar type which still occasionally appear.

At the time of writing much discussion was in progress around the whole subject of tetanus and its treatment, but the views and suggestions put forward were so numerous and so extremely varied that it was quite obvious that no very definite "best" line of treatment had been found.

Up to the commencement of the war reported cases in England were comparatively few, and even in America, where statistics of antitoxin treatment are particularly abundant, detailed reports are scarce, so that one is unable to get clear ideas of the severity of a particular case, the doses of antitoxin required, and the precise nature of the effects of the treatment on the patient.

It would seem, however, that insufficient patience and perseverance are exercised in many cases, and that one settles down too easily to the conclusion that all cases with a short incubation period are hopeless from the onset—a statement certainly borne out by a report in the *BRITISH MEDICAL JOURNAL* about the time of writing, which said: "The result (death) seems to agree with what was already fairly generally recognized—namely, that if the disease has an incubation period of less than twelve days it is fatal in spite of treatment, whether by antitoxin or other means."

A private, aged 31 years, was admitted to the Manchester Royal Infirmary in the early morning of October 31st, 1914. He gave a history of having been wounded at Ypres at 8 a.m. on October 27th by the explosion of a shrapnel shell, and on examination was found to have a large suppurating crateriform wound, extremely foul-smelling, occupying a position on the inner side of the right leg immediately below the knee-joint. A small punctured wound was also present on the anterior aspect of the joint, but the two had apparently no connexion, and the joint itself was not opened.

He stated that after receiving his wounds he had to drag himself, his leg trailing along the ground, for a distance of about fifty yards before reaching cover, and that it was not until 3 p.m. that the wound received its first dressing. He had lost large quantities of blood, and was very anaemic and toxicæmic looking when he arrived in hospital, four days after the injury. The wound was dressed with boracic fomentations every four hours, and irrigated frequently with hydrogen peroxide solution. The cavity involved the upper end of the tibia, and from time to time fragments of necrosed cancellous bone were removed.

The wound cleared up somewhat, but the question of amputation was under consideration on account of the bad general condition of the patient and the obvious impossibility of preserving a useful limb, when at 9.30 on the morning of November 5th, nine days after the injury, rigidity of the masseters was first noticed, the patient complaining of a sore throat and being found unable to open his mouth for inspection.

Previous to this, one had been on the outlook for signs of tetanus, for the patient had shown those profuse sweats which are apparently frequently the precursors of the condition, and which had been particularly marked on the previous evening.

The trismus increased rapidly and spread to the muscles of the neck and abdomen. Perspiration was profuse, so that the bed linen was soaked. At noon of the same day the leg was amputated at the middle of the thigh, partly with a view to removing the focus of infection and partly because hopes of preserving the leg were obviously small. At the time of operation about 1,000 units of antitoxin were injected into the spinal theca, and a further 2,000 units given subcutaneously. At 6 p.m. the patient had recovered from the anaesthetic, but was still very rigid about the head and neck.

The abdominal muscles were also tightly contracted, and there had been some clonic contraction of the arm muscles associated with stertorous breathing. A second anaesthetic was administered, and 4,500 units of antitoxin were injected spinally and 9,000 units given subcutaneously in the abdominal wall. Two teeth were extracted at the same time in order to facilitate the anticipated difficulty in feeding. The foot of the bed was raised and the room kept as quiet as possible.

At 1 a.m. of the following day 6 oz. of chloroform in olive oil were administered by the rectum for the continued clonic contractions of the arm muscles. Potassium bromide and chloral (55 gr. xx) were then given by the mouth at intervals of four hours. At 4 p.m. a further 15,000 units of antitoxin was given subcutaneously.

Active treatment was now temporarily suspended. The patient was fed on fluids, of which he managed to take large quantities without resort to tube feeding being necessary. His condition gradually improved, but the inability to open the mouth persisted until November 15th. A little previous to this it had been noted that the spasm relaxed slightly during sleep. On November 16th the patient took solid food for the first time. On November 17th he was given a further 15,000 units of antitoxin, 4,500 being administered spinally, 10,500 subcutaneously.

It should be noted that on each occasion when serum was given the patient's condition became temporarily much worse, there being marked increase in rapidity of the pulse and considerable rise of temperature. During the last spinal injection it is interesting to note that the patient experienced painful numbness and tingling in the amputation stump which by this time was practically healed.

Gradually the patient resumed the normal state of health—there was no return of muscular spasm, and we were able to transfer him to a convalescent hospital very shortly; there, according to later reports, he made an excellent recovery.

The points to which I would draw particular attention are:

1. Recovery in spite of well-marked symptoms and a short incubation period (nine days).
2. The large doses of serum administered, 46,500 units in all.
3. The very slow and gradual relaxation of spasm.

I am indebted to Captain E. D. Telford, F.R.C.S., R.A.M.C.(T.), in whose wards the patient was treated, and to whom I was acting as house-surgeon at the time, for permission to publish these notes.

SEROLOGICAL TESTS IN DYSENTERY CONVALESCENTS.

BY

J. C. G. LEDINGHAM, M.B., D.Sc.,

AND

W. J. PENFOLD, M.B., D.P.H.,

BACTERIOLOGISTS TO THE KING GEORGE HOSPITAL.

In a previous paper¹ we have explained that the subacute cases of dysentery which have been admitted here have all been due to infection by *B. dysenteriae* Shiga, this organism having been recovered from the dysenteric dejecta. Since that paper was published three further subacute cases have been found to be due to *B. dysenteriae* Shiga and two to *B. dysenteriae* Flexner. Only in one case so far has *E. histolytica* been present in the active form. As already mentioned, a large number of convalescent cases were admitted from whose faeces (for the most part not of dysenteric type) no organisms of the typhoid-dysentery group were recovered. There were probably 150 to 200 of these. In a certain proportion of these flagellates were found to be present in the stools, but owing to pressure of work it was impossible to analyse these cases more exhaustively. Recently, however, a fresh batch of these convalescents arrived, and the opportunity was taken to ascertain by agglutination tests with the serums of the cases what proportion of them had suffered from bacillary dysentery. The necessity for this investigation was rendered the more urgent as conflicting evidence had reached us with regard to the relative proportion of bacillary and amoebic dysentery in the Near East. The history given by these convalescents did not point invariably to dysentery, but might have been construed in some cases as typhoid infections. We have now examined the serums of over 100 of these cases, the stools in all (except one) being negative as to *B. dysenteriae*, *E. histolytica*, and typhoid organisms. The technique was that described in the previous paper. Time limit twenty-four hours.

Determination of the Upper Limit of Agglutination of *B. dysenteriae* Shiga by the Serum of Normal Persons.

It has been generally held that agglutination of *B. dysenteriae* Shiga in a dilution of 1 in 50 is significant of infection, and the statement is probably in the main true, but such statements are unfortunately not accompanied by specifications of the time limit, the method employed, and the degree of agglutination at this dilution. We therefore decided to obtain the upper normal limit in a series of serums of normal persons (generally orderlies) who had never been out of the country, and had never

suffered from dysentery. Twenty-three such have been examined under the prescribed conditions, with the following result:

- 14 gave no agglutination whatever at 1 in 50.
- 3 gave a trace of agglutination at 1 in 50.
- 3 gave agglutination amounting only to one + at 1 in 50, but no agglutination at 1 in 100.
- 3 gave agglutination amounting to one + at 1 in 50, and a mere trace of agglutination at 1 in 100.

In no case was complete agglutination at 1 in 50 with normal serum obtained.

It was decided therefore to treat all reactions above "50 (+) 100 (trace)" as significant.

Results in 103 Convalescents, the Great Majority of whom gave a History of Dysentery.

- 24 gave no agglutination in 1 in 50.
- 12 gave a trace of agglutination in 1 in 50.
- 11 gave agglutination (+) in 1 in 50, but no agglutination at 1 in 100.
- 7 gave agglutination (+) in 1 in 50, and a trace of agglutination at 1 in 100.

The above (54) fell within normal limits. Of the remaining 49 cases—

- 15 gave agglutination with end point between 100 and 200. (Illustrative reaction, 50 (+++) 100 (+) 200 (0).)
- 19 gave agglutination with end point between 200 and 400. (Illustrative reaction, 50 (++++) 100 (+++) 200 (++) 400 (0).)
- 15 gave agglutination with end point beyond 400. (Illustrative reaction, 50 (++++) 100 (++++) 200 (++++) 400 (+++), 800 (+).)

We conclude, therefore, that 49 or 47.5 of the convalescents have suffered from bacillary dysentery (type Shiga).

Dr. Woodcock, parasitologist to the hospital, found 41 per cent of these cases showed in the faeces either one or more of the following protozoa—namely, *Lambia intestinalis*, *Trichomonas*, or *Entamoeba coli*. The positive Shiga agglutination cases were not found to be more liable to harbour the above protozoa than the negative Shiga cases.

METASTATIC ENDOPHTHALMITIS IN A CASE OF CEREBRO-SPINAL MENINGITIS.

BY

LIEUTENANT A. LEONARD WEAKLEY, R.A.M.C.,

OPHTHALMIC SURGEON TO A GENERAL HOSPITAL, ALEXANDRIA, EGYPT.

I shall the following case worthy of record for two reasons—(1) the way the threatened panophthalmitis was aborted; and the quick resolution of the inflammation, possibly due to the antimeningococcus serum; (2) the cultivation of a pure growth of meningococcus from the interior of the eye.

Private H., aged 19, had pneumonia on the transport during the voyage from Australia. He arrived in Egypt on September 28th, and was sent to a convalescent hospital.

He was well until October 9th, when he had severe headache, diarrhoea, and vomiting, with rise of temperature. On October 10th the headache was worse, he became unconscious, and was admitted to hospital. He then had all the signs of meningitis: head retracted, vomiting frequently, restless, and groaning; temperature 103°. Extensor response present, and also Kernig's sign. The eyes were apparently normal, except that the right pupil was noticed larger than the left; both pupils acted to light; there was no deviation.

On October 11th, lumbar puncture showed cerebro-spinal fluid under pressure, turbid, and clotting rapidly.

Bacteriological Report.—"Fluid frankly purulent, stained films show preponderance of polymorpho-neutrophils with numerous endothelial cells and a small intracellular Gram-negative diplococcus. Culture on Buchanan's medium shows a pure culture of a Gram-negative diplococcus, morphologically indistinguishable from the meningococcus of Weichselbaum."

October 12th. The left eye was noticed to be inflamed, and when I saw the case the same morning the lids were slightly swollen, there was slight ptosis, general injection of conjunctiva, episcleral oedema, cornea hazy, Descemet's membrane covered with thin yellowish film; anterior chamber deep, turbid, and iris covered with thick grey-yellow exudate; pupil contracted, inactive to light, and completely filled with exudate; no fundus reflex obtained; globe tender; tension slightly subnormal; vision bare perception of light. There was no proptosis, and ocular movements were full in all directions. There was no discharge from the conjunctiva, and no dacryocystitis. There was partial left-sided facial paralysis.

I diagnosed metastatic infection, and, deciding that there was

no urgent need for operation, ordered atropine 1 per cent. with cocaine 2 per cent. to be instilled and hot fomentations to be applied every three hours. The right eye was quiet; pupil active to light; fundus normal; vision good.

October 13th. The pupil was still firmly adherent and tension had become raised a little. Under cocaine and adrenalin anaesthesia I washed out the conjunctival sac with sterile mercury perchloride solution 1 in 5,000 and performed a paracentesis of the anterior chamber, removing some of the pus to a culture tube of Buchanan's medium. Treatment was continued as before.

Bacteriological Report.—"Culture on Buchanan's medium shows a pure growth of an organism morphologically identical with the meningococcus."

The next day the pupil started to dilate, and on October 15th had given for three-quarters of the circumference. On October 16th it was quite free and the anterior chamber was clearing; a thick ring of yellow exudate was left on the anterior capsule of the lens. The tension was about normal and vision perception of light. The facial paralysis had practically recovered.

The eye continued to clear under local and general treatment, and on October 20th the pupil was well dilated, episcleral swelling subsided; tension was about equal in both eyes, and both subnormal. Vision=hand movement. No fundus details could be made out, and only a yellow-green reflex obtained. On convergence the left eye already diverged. The local treatment was now dionine 0.0005 gram, atropine 1 per cent. every six hours, and fomentations as before. A culture taken from the conjunctival sac showed a growth of *Staphylococcus albus* and no meningococci.

On October 27th the eye was quieter; the pupil was dilated, with one small adhesion at ten o'clock. The anterior chamber was clear, the lens capsule nearly clear, the vitreous clearing; only greenish-grey reflex and gross floating opacities were made out. Vision was perception of light, and becoming worse. Atropine and dionine now only bare dilatation.

On November 1st the eye was quiet, the iris showed several snail-track-like grey eroded patches scattered around, the anterior chamber was clear and of medium depth, anterior part of vitreous fluid clear, and a large yellow-green mass was seen floating in upper quadrant; neither vessels nor disc could be seen. The tension was -1 and the vision perception of light, and the eye was apparently beginning to shrink. The general treatment has been to draw off 15 to 20 c.cm. of cerebro-spinal fluid from the lumbar region and replace with an equal amount of antimeningococcus serum about every two days, according to symptoms. The patient has steadily improved in general health, and is apparently now on the road to recovery.

THE DOMICILIARY TREATMENT OF PULMONARY TUBERCULOSIS.

BY

G. H. DART, M.D., M.R.C.P. EDIN., D.P.H. CANTAB.,

TUBERCULOSIS OFFICER AND ACTING MEDICAL OFFICER OF HEALTH, METROPOLITAN BOROUGH OF GREENWICH.

IN view of the fact that at the present time there is very little, if any, institutional means in most of the London boroughs for dealing with advanced cases of pulmonary tuberculosis—apart, that is, from the general hospital or infirmary—the question of how to deal with advanced cases in their homes is of the greatest importance.

London boroughs vary very much both in administrative schemes and in the character and variety of local agencies dealing with tuberculosis, but in a few respects at least the facts with regard to Greenwich may have some value for every borough.

It appears from a comparison between the number of deaths and the number of cases nursed in Greenwich that many more than half the patients who died at home did not receive skilled nursing attention.

The deaths from pulmonary tuberculosis numbered 129 during 1914 in Greenwich. Of these deaths, 50 occurred in Poor Law and similar institutions, 17 in hospital, and 62 at home. The number of cases nursed during 1914 was 46, and 24 of these cases died during the year. There are three district nursing associations in the borough, employing in all 12 nurses.

At first sight this return, as far as regards the places where death occurred, appears satisfactory, as more than 50 per cent. of the deaths have taken place in institutions. Also, although there were 62 deaths at home, 46 cases had nursing supervision, with its attendant prevention of the spread of infection. It appears, however, that many of the cases nursed were not among the deaths. Satisfaction with the return is also modified by the fact that many of the patients shown as having died in an institution in reality required nursing—many of them before entering

and many after leaving or before re-entering the institutions.

The leaving notifications (hospital and infirmary) during 1914 numbered 48. There were 24 deaths among these patients. Of these deaths 5 occurred at home, and 3 of the home deaths had the benefit of nursing. The remaining 19 deaths took place in institutions, and 2 of these patients during the period between their discharge and return were nursed.

These 19 returned patients are, of course, included in the 67 patients who died in institutions, and who, therefore, at the first glance, might be considered as not having needed nursing.

A patient who "takes his discharge" from an infirmary or hospital and becomes so rapidly worse that he dies within the year, in all probability requires home nursing, whether he dies at home or enters the infirmary to die. The large majority of institutional deaths take place in the infirmary.

These patients prefer, as a rule, to stay at home until desperately ill and leave the infirmary on the slightest pretext.

The result of this is placed on record in the Final Report of the Departmental Committee on Tuberculosis: "Infection is frequently disseminated by persons suffering from advanced pulmonary tuberculosis who are in the habit of entering and leaving Poor Law institutions, having regard merely to their own convenience, and not to the interests of their family or of the community in which they live."

Considering the advanced character of the disease in most cases treated in these institutions, it would probably, therefore, be nearer the mark if one considered all such cases in need of nursing after discharge. Certainly, if, as in Greenwich in 1914, 50 per cent. of these cases die during the same year, it is probable that the majority of the survivors have been during the year in need of attention.

If the 48 leaving notifications, minus the 5 patients that died at home, are added to the total 62 deaths at home, 81 per cent. of the total deaths will be found to have required nursing during 1914.

The greatest number of visits paid to a patient was 60. The average, obtained from the total numbers of patients and visits, worked out at 20 visits a patient.

The work cannot be carried out by dispensary nurses unless the number attached to the dispensaries is greatly increased. If for the purpose of estimating the number of visits required one takes, not the 81 per cent. mentioned above, but only 66 per cent., or, say, two-thirds of the deaths, at an average rate of 20 visits to each patient, the estimated number of visits would in many instances approach the number of visits actually paid by the nursing staff. As an illustration:

	Deaths.				N.	Visits.	
	Total.	P. L. I.	H.	D.		C. F.	A.
Paddington ...	156	42	35	79	664	2,925	2,080
St. Marylebone ...	149	87	15	47	526	2,219	1,986
Stepney ...	447	198	55	194	2,038	10,016	5,960

Total = Total deaths 1913. P. L. I. = Deaths in Poor Law institutions. H. = Deaths in hospital. D. = Deaths at home. N. = Primary pulmonary notifications. C. F. = Central Fund report visits paid. A. = Estimated visits to advanced cases.

To attempt the nursing from the dispensary of those who died at home, even if such a small number of visits as to average 20 per patient were paid, would in itself be sufficient to cripple the work in connexion with other than advanced cases.

The Greenwich Dispensary had not completed a full year in 1913. Throughout 1914 the nurses did not attempt any home nursing, even of bed-ridden patients who had formerly been dispensary patients.

Greenwich, 1914.	
Deaths ...	129
Primary pulmonary notifications ...	308
Visits paid ...	3,676
Visits estimated to two-thirds of the deaths at above rate ...	1,720

The deaths alone, moreover, give no indication of the

number of patients who survive for a more lengthy period, and who also require nursing during relapses.

If to the 62 home deaths were added the 22 nursed cases who survived the year and the 38 "leaving notifications," after subtracting the deaths at home and the number nursed from the total "leaving notification," the estimated number of visits to 122 cases would be 2,440. Perhaps if this number were doubled it might indicate, as far as regards last year's figures, the amount of work required in endeavouring to prevent the spread of infection by these cases.

At least two additional whole-time nurses would be needed at Greenwich if this work were to be attempted from the dispensary. The Greenwich Dispensary nurses visit all notified patients of every description, and the district nurses are informed of those cases requiring home nursing. The dispensary nurses were formerly Ranyard nurses, and are in close touch with the Ranyard Association.

In spite of this, however, it is evident that a considerable number of cases do not receive adequate attention, and many no attention at all. Some of the patients move out of the district of the particular nurse who has been in attendance. Many patients who receive nursing aid recover to some extent and ask the nurses to cease calling; a later relapse is followed by a call for the doctor, but not for the nurse; and, from the point of view of prevention, careful nursing of these cases is of much greater importance than medical aid. Careful nursing, backed up by medical authority, is essential. Both for the sake of the patient and of the community domiciliary treatment should always include skilled nursing in addition to medical advice. Many other patients refuse help from the nurses, or other members of the family object.

A closer connexion between the nursing associations and the public health administration might obviate some of these difficulties, and arrangements to this end are now under consideration in Greenwich. Perhaps the most desirable arrangement would be that the actual nursing of a patient receiving domiciliary treatment should be carried out by a nurse from the dispensary appointed to deal with advanced cases, and that a health visitor should keep the case under observation when actual nursing was not required, all, of course, under medical supervision.

Since it is generally accepted that "there can be no manner of doubt that the far advanced or dying cases constitute the greatest source of infection," it follows that any scheme for the prevention of tuberculosis which does not deal adequately with these cases will fail in its object.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

WOUND DRESSING.

Should a wound arrive in a very foul condition it should not be covered with a dressing directly applied. A patty pan, having a hole about the size of a shilling punched through its centre, should first be placed over the wound. Patty pans cost 2d. or 3d. a dozen at the ironmonger's, and can be bent by hand to the shape of the part. They have rolled-over edges, and lie smoothly and comfortably on the sound skin remote from the wound. Dressings are applied outside the pans. Nothing, therefore, touches or blocks the wound itself, and discharges freely flow into the hollow of the pan and its covering dressings. When desirable the pan is held in place by one or two strips of strapping passing across its edges. All the discharge will be found in the hollow of the pan and the dressings, and practically none in the burrows of the wound, at the subsequent dressing. The pan can be boiled and used again.

A wound should be syringed out from the bottom if it extends deeply. To this end the ordinary syringe nozzle should be replaced by 6 in. of thin copper tubing, say $\frac{1}{8}$ in. in diameter. For convenience the tube should be bent near its screw attachment through an angle of about 60 degrees and its free end rounded with a little solder.

For syringing, as a general rule, hypochlorous acid, the 2½ per cent. solution of Professor Lorrain Smith and his coadjutors (eusol), should be used, and the wound dressed

by applying a pad of gauze moistened with eusol, and folded to the size of the wound treated. This is covered by a similar pad of wet wool, which holds liquid better. Over this should be placed a piece of waterproof tissue, slightly larger than the dressings beneath. Finally, a good pad of cotton-wool should be applied, extending well beyond the waterproof tissue, especially below it in the line of drainage. The size of the waterproof tissue is not unimportant as it determines that of the wool which has to project beyond it sufficiently far to absorb any discharges escaping from beneath the impervious material. In war especially economy is a virtue, and the effort to attain it encourages attention to detail. Thus treated, a wound should be clean and healthy in two or three days, if free from any foreign body or dead bone.

The best waterproof tissue procurable can be made by any one for 6d. a square yard, about one-fourth the usual price. I buy a length—say 30 yards—of "madapolin" (a thin strong calico) 42 in. wide, at 4½d. a yard. I tear it into yard lengths, and dip a piece at a time into cold boiled linseed oil. This I wring out by hand, and wipe off any surplus oil from the twisted mass and my hands with the yard of dry madapolin next to be treated. The oil-soaked piece is hung up on a horizontal wire by three safety pins, and the following day is hung the reverse way up. A second reverse is generally desirable. The whole dries in a week in an open shed, or in about ten days in a garage in winter.

The hospital of 200 beds with which I am connected uses little else to cover wet dressings or protect splints since I introduced it. The same piece is commonly used repeatedly, as it stands scrubbing well.

SODIUM SULPHATE IN DYSENTERY AND INFANTILE DIARRHOEA.

IN the JOURNAL of November 13th Dr. Penfold refers to the discovery of the *B. dysenteriae* (Flexner) in two cases of infantile diarrhoea under his care and to its recognition by others in similar cases. I have for several years regarded infantile diarrhoea as so closely allied to pure bacillary dysentery in children that I have invariably submitted them to the same treatment.

This consists, briefly, in the administration of sodium sulphate in doses, for children under 1 year, of 5 to 15 grains every two or three hours. A preliminary dose of castor oil is valuable in all cases. Milk is generally excluded from the diet for a few days. Under this treatment the mortality from this disease in my own practice has been reduced to an almost negligible percentage.

In the cases of dysentery occurring amongst the Mediterranean Forces, failure to find any one special bacillus as a causative agent appears to have been frequent in laboratories, owing probably to the bacteriological examination being made after the disease has existed for some time, as the dysentery bacilli very quickly are crowded out by other intestinal species. Experience of bacillary dysentery in the tropics has convinced me that the administration of bismuth and opium should be avoided, and that the treatment by 1-drachm doses of sodium sulphate every hour or two is to be preferred to every other. The frequency of dosage is modified as the pain and tenesmus lessen, and the character of the stools, as shown by the disappearance of blood and mucus, improves. The drug should be continued for some time after the stools have become entirely free from a trace of blood or mucus. No harm, but rather good, will result from the patient having three or four loose stools daily.

Both amoebic and bacillary dysentery respond at once to this treatment, but should amoebae be found later in the stools emetine should, of course, be administered. It is unnecessary otherwise. The earlier the treatment is adopted the more quickly and completely patients will recover.

W. J. J. ARNOLD, B.A., M.B., D.P.H.

THE Royal Dental Hospital, Leicester Square, has received a donation of £2,000 from the trustees of the late Miss Harker-Smith. The Chelsea Hospital for Women has received a legacy of £1,000 bequeathed by the late Mr. John Samuel White.

Reports of Societies.

THE WORK OF A CONSULTING SURGEON WITH THE BRITISH FORCE IN FRANCE.

A SPECIAL meeting of the Ulster Medical Society was held on December 21st, 1915, in the Medical Institute, Belfast, under the chairmanship of the President, Dr. GARDNER ROBB, to hear an address by Colonel ANDREW FULLERTON, one of the Consulting Surgeons to the British Expeditionary Force in France, on his experiences of war surgery. Colonel Fullerton received a hearty welcome on rising, and, after a few introductory remarks, proceeded. The work of a consulting surgeon, he said, varied according to whether he was placed in charge of a number of casualty clearing stations or of base hospitals. His own experience was that of a large base with a considerable number of stationary and general hospitals. These hospitals or units were in charge of a commanding officer, usually of the rank of lieutenant-colonel, with a major as second in command. The commanding officer was responsible for everything connected with his unit. There were attached to each hospital one or two surgical specialists, and, generally, several junior surgeons and physicians, as well as x-ray specialists and pathologists, the whole forming a first-class hospital, comparing favourably with some of the best general hospitals at home. The surgical specialists were highly qualified surgeons, and the work done by them was of a high order, and reflected great credit upon the service of which they were temporary members. Most of the regular R.A.M.C. officers were doing administrative work, but several of those who were surgical specialists before the war were retained in their positions. The work of these officers also was of a very high order. The x-ray work was good, and in one or two hospitals was as near perfection as could be. The help given by the pathologists in every case in which it had been sought had been of inestimable value.

It would be readily understood that every day cases cropped up in which a second opinion was desirable or necessary, and Colonel Fullerton said that the system of consultants worked with the utmost smoothness in his area. The more competent the surgeon, the more desirous he was of talking over his difficult and dangerous cases with the consultant. Cases were constantly arising in which it was desirable that the consultant should himself operate, and every facility was placed at his disposal for the discharge of this duty. The consultant was, in fact, responsible for all the surgical work done in his district, and he was usually fortunate in the officers over whom he had supervision.

Colonel Fullerton said that he had had the opportunity of seeing the work of the field ambulances and the casualty clearing stations, and traced the progress of the wounded man from the firing line to the base. He paid a high tribute to the wonderful organization of the R.A.M.C., which had covered itself with glory in its fight with injury and disease. Nothing could exceed the smooth working and efficiency of the organization which transferred the wounded soldier from the trenches to the base or the hospital ship. The wounded soldier himself was loud in his praise of the officers, orderlies, and nurses, who took care of him from the moment he was carried in from the field until he was safely deposited, warm, well fed and clothed, in his hospital bed.

Colonel Fullerton then went on to speak of the surgical work carried on in his own district, and illustrated his remarks by a large series of lantern slides. Some of the x-ray photographs were of a high degree of excellence, and reflected great credit on the x-ray specialists. In connexion with injuries to the head, he stated that the War Office, recognizing that special work in this department would be invaluable to the army, had appointed two distinguished neurologists—physician and surgeon—as consultants in this branch of surgery, with the happiest results. Sepsis in brain surgery—as, indeed, in all branches of war surgery—was the bugbear of the surgeon, and required even more attention than operation. Deep searching for foreign bodies in the brain was discouraged, and a bullet that was causing no symptoms was left alone if not easily accessible. Excision of the septic wound, as far as possible, was carried out with good results.

Persistent hernia cerebri was treated by lumbar puncture or decompression operations.

The knee-joint was one of the greatest trials of the military surgeon. If the patella were shattered it ought to be removed. If the lower end of the femur or the upper end of the tibia were badly comminuted it was probably better to amputate at once above the knee. The question of the removal of foreign bodies from the knee-joint was a difficult point. Rough particles, like shell and bullet casing, had probably carried in bits of soiled clothing with micro-organisms, and were better removed, but each case must be considered on its merits, and the judgement and experience of the surgeon would often be taxed to decide on the proper procedure. Swollen septic knee-joints, with no fracture and no retained foreign body, offered a problem requiring abundant experience, and he had made it a point to see every available case and watch its progress. He had come to the conclusion that indiscriminate draining of knee-joints with tubes was a mistake. Fixation, excision of the wound, aspiration and washing out with saline, aspiration and injection of such substances as ether, formalin, and glycerine, etc., simple incision without the use of a tube, packing of the joint with gauze, laying open the joint by turning back the patella, with, perhaps, full flexion of the joint, were all measures useful in different cases. Failing benefit from these, amputation was the only resource.

In the hip it was occasionally necessary to remove the head of the bone in order to drain the joint, and he described several cases in which life had apparently been saved thereby. In the shoulder and elbow excision had been followed by good results.

The means employed to immobilize fractures, as used in France, were described, and it was said that the main objects the surgeon had to keep in view were fixation, drainage, and sterilization of the wound. The last was the most difficult, and in some cases was impossible.

Finally, slides showing the splints in general use in France were exhibited, including Major Sinclair's apparatus for suspending limbs in splints, and Captain Bryan's segmented suspension bed for the treatment of patients with wounds in the back, buttocks, etc.

Opinion in France was divided as to the best antiseptic. Wright's hypertonic saline was lauded by some, esol by others, while a third set of surgeons had almost lost faith in antiseptics, though they were willing to try anything that might be suggested. While micro-organisms were easily enough killed in a test tube, the problem of their destruction in the tissues was quite another matter.

A very hearty vote of thanks to Colonel Fullerton for his address was suitably proposed by Professor Sir JOHN BYERS, seconded by Dr. J. WALTON BROWNE, supported by Mr. A. B. MITCHELL, F.R.C.S.I., and enthusiastically passed.

Reviews.

FEEBLE-MINDEDNESS.

DR. GODDARD has been for some years Director of the Research Laboratory of the Training School for Feeble-minded Girls and Boys at Vineland, New Jersey. There free from the routine work of administration and from the medical treatment of the patients, he has organized a school of research, and his book on *Feeble-mindedness* is in the nature of a report on the work of the laboratory staff of the first five years in an attempt to discover the causes of feeble-mindedness from an examination of the 327 cases in the institution. It is not claimed that the report is complete, but rather that it is a preliminary statement of results.

As regards the consequences arising from mental defect, the writer opens with a working hypothesis which he states as follows:

There are all grades of responsibility from zero to the highest; and there are all grades of intelligence from practically none up to that of the genius or the most gifted. Responsibility varies according to the intelligence. Responsibility and normality of intelligence are relative to the environmental conditions.

¹ *Feeble-mindedness: Its Causes and Consequences.* By H. H. Goddard, Ph.D. New York: The Macmillan Company. 1914. (Demy 8vo, pp. 611; illustrated. 17s. net.)

Responsibility can be measured by measuring the intelligence, and knowing the degree of responsibility we know how to treat.

The defect of function is due to incapacity, not to a failure of will.

It is, however, in the question of the application of the Mendelian law to the problem of mental deficiency that the interest of the book mainly centres, and to this our principal attention may be devoted here.

The greater part of the book—nearly 400 pages—is occupied with a record of cases; these are admirably described and freely illustrated with photographs of the individuals and examples of things written or drawn by them. Each case record is accompanied by a chart giving the information as to the condition of other members of the family, obtained from relations or the family doctor and supplemented by the personal inquiry of field workers—that is, ladies specially prepared for the work who have gone to the home and personally followed up all available sources of information. These charts are one of the distinguishing features of the book; another is the fact that the cases are not selected but comprise all those residing in the institution; and the third is the mode of classification of this material.

The main grouping is on the basis of probable causation. The causes assigned are: (1) Feeble-minded heredity; (2) neuropathic (as opposed to feeble-minded) family conditions; and (3) accident. There are some cases for which no cause can be discovered and a few which cannot be classified; but a large majority are, on the strength of the evidence supplied by the family history charts, grouped as hereditary or probably so—namely, 198 out of 327. Within the groups the cases are arranged in order of their so called mentality; by this is meant the result obtained by the application of a Binet test, which gives an approximate measure of the intellectual endowment of the individual. The intellectual age of the cases thus estimated ranges from correspondence with that of a child of 12 (of which there is one example), down to the condition of an infant 1 year old. The whole constitutes a storehouse of valuable material, well worked out and conveniently arranged.

Several chapters follow in which the data provided by the charts are tabulated and discussed, mainly from the point of view of causation, and concluding chapters are devoted to eugenics and practical applications. As to the general tendencies of these and the main conclusions reached, we may for the most part agree with the author, especially as in the main they do not differ materially from the conclusions reached by other writers on grounds less fully elaborated. This applies in particular to the predominating influence of heredity in the causation of defect, and similarly in regard to the effects of environment, alcohol, criminality, syphilis, consanguinity, etc., and undoubtedly the facts and figures here arranged give additional strength to the conclusions arrived at.

The author himself admits that the data are incomplete, and asks us not to look for mathematical accuracy in a field like this: "The physician who waited until the facts on which he bases his diagnosis were absolutely proved would often wait until the patient was dead." With this we agree, and for most practical purposes the general conclusions pointed to may be, if they are not already being, acted upon. But when we are asked to formulate precise scientific doctrines as to the working of inheritance we are in no such urgent hurry, and we can afford to wait until the facts on which we build are clearly ascertained.

Dr. Goddard disclaims at the outset any preconceived opinions, though admitting the existence of impressions and feelings that he and his workers would find such and such things. It was therefore highly important that the evidence and the conclusions drawn from the evidence should be kept most rigidly apart. One cannot help regretting, therefore, to find such expressions as the following: "The best evidence of accuracy in the data will be discovered by a study of the charts themselves and the figures that have been compiled from the charts." This seems to betray a confused attitude towards scientific accuracy, and confidence is not restored on reading in one of the introductory chapters: "It is perfectly clear that if both parents are feeble-minded all of the children are feeble-minded. This being true, we had a right to mark all of the children on our first chart

in this case feeble-minded, since both parents are in this condition. But we have never done this." The mere suggestion that in a piece of inductive work such as this aims to be it might be considered right to modify the data in accordance with conclusions deduced from the material under examination is, to say the least, startling. Again, why should the fact that a father was entirely unknown to his wife's family be regarded as laying his mental condition under suspicion? So, too, in an investigation of this kind one has no right to invoke the type of the child as evidence of its hereditary origin. Again, why should a writer who takes a purely intellectual standard of deficiency attach importance in the charts to the fact that an individual was ugly or of a heartless disposition?

In the three chapters devoted to the Mendelian theory in relation to feeble-mindedness, the figures obtained from the data are analysed on the hypothesis that feeble-mindedness is a recessive Mendelian unit-character due to the absence of a determiner for normal mentality. We are practically all agreed that defect is to a very great degree inherited in some way or other; many also are disposed to accept the view that intelligence comprises both a general factor on the one hand and various special factors on the other; but the adoption of the view that mental deficiency can be regarded as a unit-character obedient to Mendelian laws carries with it difficulties and implications which demand for its acceptance full and positive proof.

As an example of implications that flow from the idea of a unit-character, the presence of other characters, which will, *ex hypothesi*, be inherited independently, can have no bearing on the feeble-mindedness unit; thus it would not be fair to count sexuality, ugliness, epilepsy, bad disposition, melancholy, migraine, or alcoholism in an individual as if they had a bearing on the transmission of mental defect. Hence the noting of such facts as that a person in the charts "committed suicide," or "was killed in a railway accident," must not be allowed to affect the consideration of this point however interesting they might be from other aspects.

On turning to the figures, it is found that an examination of the various matings recorded in the charts of the cases which the writer has placed in the hereditary group shows that there were 144 examples of a defective mating with a defective, while the records show that 65 per cent. of the offspring are known to have been defective, and only 0.8 per cent. are known to have been normal; this is sufficiently near to the requirements of the Mendelian law that all such children must be defective, that we may let it pass with the remark that it is the result that would be anticipated by almost any theory of heredity, and whether the defect were a unit-character or no.

When the writer comes to deal with matings of other types he finds 324 out of 1,345 that can be used for his purpose. He then says: "When both parents are duplex all of the children must be normal. Of course we have nothing to do with this type of mating in a defective family." This appears to beg the question at issue. There are numerous matings recorded between normal persons with nothing in the facts to show whether they are duplex or simplex—that is, whether they do not or do carry a latent strain of defect.

The method adopted in dealing with these and other types of mating is "to assume the law, then see if the conditions as we find them can be accounted for on this assumption." "There have been two methods of determining the simplex inheritance of the parents; in some cases it has been the study of the ancestors, in others it has been the condition of the offspring." Here again the writer seems to be unaware that this is simply begging the question and making uncertain data conform to requirements, instead of checking them by further investigation of the facts.

On an examination of sixty-four charts—Nos. 133 to 197—which are included in the Hereditary and Probably Hereditary groups, we find thirty-seven matings in which one of the parents is normal and the other either defective or of undetermined mentality, and to which at least one feeble-minded child has been born. For this to be in accordance with Mendel's law it is necessary that the normal parent should have latent mental defect. For a pure duplex normal would have no patently defective children in the first generation. In none of these cases is there any evidence in the data to show that these normal

parents carried any defective strain. These matings are not all included in those analysed, but wherever it is necessary for the author to assume a latent defect this is done, on the presumption that latent defect may be taken for granted in half the cases. In the same charts there are 10 cases also in which a feeble-minded child is recorded to have normal or probably normal parents, in regard to whom there is no evidence that both are simplex, as required by the law.

The author confesses to being one of those psychologists who find it hard to accept the idea that the intelligence ever acts as a unit-character, but he finds no way to escape the conclusion of the figures. May it be suggested that the best defence against the figures lies in the facts? What is wanted is further "field" work to test the assumptions made. For our part we feel bound to suspend judgement till this is done.

THE PHYSIOLOGY OF THE EMOTIONS.

The eight papers which Professor CRILE has brought together under the title of *The Origin and Nature of the Emotions*,² deal with as many at first sight distinct subjects, but the underlying unity of aim is not far to seek. There is, as was inevitable, a certain amount of overlapping and reiteration, but, inasmuch as each essay reveals a new aspect and a broadened application of the main principles which the author seeks to establish, the book loses nothing of interest on that account. Professor Crile has devoted many experiments and much thought to the problem of shock, which he has come to regard as a state of exhaustion of the brain centres caused by impulses entering the system through the receptors for pain, which Sherrington designates "nociceptors." He finds that the abdomen and chest when traumatized stand first in facility for causing this discharge of energy, that is in shock production, being followed by the extremities, the neck and the back, while the brain and other protected parts give no such response. This suggests the natural selection of regions much exposed to injury from without as sites for nociceptors, as the discharge of energy which culminates in shock is previously available for purposes of flight or resistance; "the greatest shock," he says, "is produced by any technic which imitates the method of attack and of slaughter which is used by carnivora." He finds that armoured animals are comparatively immune to both shock and fear, and that in general proneness to fear, distribution of nociceptors, and susceptibility to shock go hand in hand. The nerve-muscle reactions which, preceding the exhaustive stage (shock), follow stimulation of nociceptors are specific and purposive. In the case of civilized as contrasted with savage man, direct reaction to injury or to disturbing conditions in general is, however, subject to all sorts of restraint. Emotion the author regards as a state in which the resources of the organism are mobilized for an action which cannot or does not ensue. Such an action would be specific to the stimulus and racial in origin—"a phylogenetic fight is anger; a phylogenetic flight is fear; a phylogenetic copulation is love." To us it seems that these are mere feelings, comparable to those of caged animals, and that the difference between such feelings and the distinctively human emotions is qualitative, not a mere matter of degree. In emotion there is, or may be, a leaven of ideality, for which, *pace* Professor Crile, no mechanistic explanation can conceivably suffice. It is surely characteristic of the emotions that they energize the intellect and will, and are not limited to self-regarding modes of expression. But, then, Professor Crile does not believe in intellect or will otherwise than as products of an all-creative environment. In one of these papers, entitled "A mechanistic view of psychology," he asserts roundly that "if the full history of the species and of the individual could be known in every detail, then every detail of that individual's conduct in health or disease could be predicted." Such statements are as easy to make as they are impossible either to refute or substantiate.

Space forbids more than mention of the interesting and suggestive sections which deal with headache and other

pains in certain forms of infection, the clarifying functions of laughter and weeping, the relation of acidosis and hydrogen-ion concentration to anaesthesia or death. But we would call special attention to the address on the kinetic system, in which evidence is adduced that, in regard to the production and output of energy, the stress of life is shared by a chain of organs consisting of the brain, the adrenals, the liver, the muscles, and the thyroid gland.

This thought-provoking volume cannot fail to enhance its author's already high reputation as a physiologist, and will be read with pleasure not only on account of the value of its matter but also for its picturesque force of style.

EMBRYOLOGY.

In his *Manual of Embryology*³ Professor PATERSON has evidently sought to set before the student the fundamental facts of this science in as simple a fashion as possible. Minutiae have been rigorously excluded wherever this could be effected without injury to the conception which the student should possess of embryological processes. Further, the facile pencil of the author has been pressed into the service, and a large number of simple and ingenious diagrams help the student in his progress through the text. In a book of this character there must necessarily be omissions; there is little room for theories, while all doubts are hidden under a vigorous didacticism, as, for example, in the account of the developmental changes occurring in the region of the cloaca. Such features are, however, part and parcel of the book, and were, no doubt, intentionally selected, the author's aim being to give the medical student a fair and complete working idea of the subject in the short period available in the curriculum for its study. If the book is open to any criticism it is that for the sake of simplicity there is at times a somewhat unnecessary sacrifice of reality, and we think that if the author were in a future edition to replace some of the diagrams with figures drawn from nature he would increase very considerably the value of the book. We would suggest that in Fig. 27 the embryonic stalk should be shown, and that in Fig. 263 anachronisms might be avoided. In a number of the diagrams dealing with the chorion, the venous sinuses appear between the chorion and decidua instead of actually within the latter. These are, however, small blemishes, and do not seriously detract from the solid virtues of the book. Within his self-fixed limits the author has, in our opinion, given us the most concise and clear account of the subject in our language, and the book can be warmly recommended to the hard-worked and over-driven medical student as a book which is likely to mitigate both his labour and distress. While the book is primarily a book for students, both its plan and its diagrams will afford teachers of the subject no little assistance in the arts of arrangement, compression, and simplification.

In his *Laboratory Manual and Textbook of Embryology*⁴ Professor PRENTISS has supplied us with a book which has as its special feature an account of a method of dissecting pig embryos, with descriptions and illustrations of the dissections. With these are given for comparison dissections of reconstructed wax models, the result being that the student obtains the clearest possible conception of the changes which occur during, at any rate, the later stages of development. In addition to this special section, the author gives a clear and concise account of the development of the human embryo and of the more important stages in the development of the chick embryo. The book is excellently illustrated, and although the majority of the figures are borrowed from other works, quite a considerable number are original, drawn from specimens in the collection of the North-Western University Medical School. The book is of convenient size, and gives the medical student, for whom it is specially designed, all the information he requires. To him, as well as to the research worker, the book can be warmly recommended.

² *The Origin and Nature of the Emotions*. By G. W. Crile M.D. Miscellaneous papers, edited by Amy F. Rowland, B.S. Philadelphia and London: W. B. Saunders Co. 1915. (Med. 8vo, pp. 240; 76 figures. 13s. net.)

³ *Manual of Embryology*. By A. Melville Paterson, M.D. F.R.C.S. London: H. Frowde, and Hodder and Stoughton. 1915. (Cr. 8vo, pp. 401; 304 figures. 10s. 6d. net.)

⁴ *Laboratory Manual and Textbook of Embryology*. By C. W. Prentiss, A.M., Ph.D. Philadelphia and London: W. B. Saunders Co. 1915. (Sup. roy. 8vo, pp. 400; 368 figures. 17s. net.)

A STRAIGHT TALK FOR ADULTS.

NOVELISTS who set out to write novels with a purpose and a lesson to teach may be divided into two classes—those, namely, who appeal to the reading public by the excellence of their art, and those who rely rather on the extravagant violence of their statements. As obvious examples of writers of the first class may be mentioned Charles Reade, author of *Hard Cash*, and Mrs. Harriet Beecher Stowe, author of *Uncle Tom's Cabin*; both these novels had intrinsic literary merits to account for their success. As an instance of novels of the second of the two classes mentioned above, a recent American production by UPTON SINCLAIR may be quoted, *Sylvia's Marriage*,⁵ in which the author sets out to expose the alleged extent to which venereal disease is prevalent in the United States, and how this alleged prevalence is to be combated. Like certain other popular American authors, Upton Sinclair is a red-hot writer with the utmost violence of thought and expression at his command, when he so desires it; when he adopts the style of the shilling shocker, as in the present instance, he undoubtedly succeeds in giving the reader at least a guinea's worth of shock for his shilling. In *Sylvia's Marriage* the cruder aspects of gonorrhoeal disease are forced upon the reader as they strike a hard-bitten self-educated American divorcee of 47. The author quotes, and appears to endorse, the statement that 85 per cent. of the pick of America's young manhood are infected with some venereal disease while at their universities, and that "this is what is going on" "in every prep-school dormitory in America." In the pages of this novel we are introduced to mothers who encourage their sons to intrigue with mulatto girls; to medical men who do not recognize ophthalmia neonatorum when they see it, and have the strangest ideas of professional secrecy; to a state of society where temperance and continence are apparently unknown to the young men. Whether such exaggerations as these serve any useful purpose seems to us more than doubtful. No sensible person wishes to deny the existence of the social evils caused by venereal disease at the present time; but is it to be believed that any good will result from discussing their coarser aspects in stentorian tones from the house-top? The author appears to imagine that vice in the male will be lessened by instructing females in the grosser of its evil effects. To this proposition we cannot assent.

NOTES ON BOOKS.

HIS many admirers will welcome the volume of addresses which Sir DYCE DUCKWORTH has published under the title of *Views on Some Social Subjects*.⁶ Medicine occupies an intermediate position between the spheres of thought and action. This makes it, however, in many ways more conducive to the development of a philosophical temper than a life purely devoted to either. There is a good deal of truth in the saying that "Lookers on see most of the game." Yet medicine has always proved herself a jealous mistress—was it not on her behalf that a Master complained of the brevity of life?—and perhaps this accounts for the fact that very few of those who have risen to the top of the professional tree have done really great things in literature. For Sir Dyce Duckworth the writing of these addresses has evidently been a pleasant by-activity. After reading one or two of them one knows in advance what the author's verdict will be on the remaining topical controversies indicated in his list. He is always strong in his allegiance to authority and tradition. In dealing with the alcohol question he is for temperance, not abstinence; recalcitrant woman is gently but firmly assured that public affairs are no concern of hers; he will not concede any substance to the attacks made upon formal religion by representatives of the higher criticism, and of science. All is calm, sane, orthodox; but no better book could be recommended to any intelligent layman who wished to make a psychological study of the strength as well as the limitations of a typical professional mind. The opening address, "Knowledge and Wisdom in Medicine," is one of the best and most characteristic, but it is disconcerting to find the author, on p. 31, apparently identifying wisdom and

"strong commonsense." Doubtless the verdicts of wisdom and commonsense will concur more often than not; none the less, on many occasions and on questions of vital moment they have been opposed. As expressions of the author's own wisdom, based on something deeper than commonsense, these addresses sound a useful note of warning to an age seething with revolutionary ideas.

So many misconceptions are abroad as to the real aims of the movement inaugurated by the late Sir Francis Galton that it is highly desirable that the general public should be enlightened thereon, and Dr. SALEEBY in *Progress in Eugenics*⁷ has produced a manual which cannot fail to be of considerable service. He recognizes three departments of eugenic endeavour—positive, negative, and preventive. The first of these is concerned with the encouragement of worthy parenthood, the second with the discouragement of unworthy parenthood, and the third with the protection of all parenthood from the racial poisons—for example, venereal disease, lead, alcohol. The antithesis of "nature" and "nurture" of which we hear so much is for all practical purposes false; it is useless to provide for the birth of healthy children if we take no steps to secure their remaining healthy after they are born. Another fallacy is that which regards slum life as a defensible phenomenon inasmuch as its conditions are supposed to favour the elimination of the "unfit." For the survivors are assuredly damaged, and the moral and physical welfare of the entire community are impaired by the contagium of which every slum centre is a fruitful source. Dr. Saleeby's book has grave faults of manner; he writes too often in an *ex cathedra* tone which irritates the reader by its tacit suggestion that he is in a state of culpable ignorance upon matters as to which the author alone is in a state of grace. This is the more regrettable as it tends to create some prejudice against a book which is fundamentally sound and meritorious.

⁷ *The Progress of Eugenics*. By C. W. Saleeby, M.D., Ch.B., F.R.S., F.R.S.Edin. London and New York: Cassell and Co., Ltd. 1914. (Demy 8vo, pp. 263; illustrated. 5s net.)

NEW YEAR HONOURS.

THE following are among the members of the medical profession mentioned in the New Year honours:

K.C.M.G.

Surgeon-General Sir James Porter, R.N., M.D., K.C.B., Honorary Physician to the King, late Director-General, Medical Department, R.N.

Temporary Surgeon-General Sir William Watson Cheyne, Bt., R.N., M.B., C.M., Honorary Surgeon-in-Ordinary to the King.

K.C.V.O.

Surgeon-General Sir Anthony Bowlby, K.C.M.G., F.R.C.S., Surgeon-in-Ordinary to the King.

Knights.

George Andreas Berry, M.B., F.R.C.S.Edin., Honorary Surgeon-Oculist to H.M. the King in Scotland, Consulting Ophthalmic Surgeon Edinburgh Royal Infirmary, Ophthalmic Surgeon 2nd Scottish General Military Hospital, and ex-President of the Royal College of Surgeons of Edinburgh and of the Ophthalmological Society of the United Kingdom.

Thomas Wright Parkinson, M.D.Edin., Physician to H.R.H. Princess Louise of Battenberg and to Admiral Prince Louis of Battenberg. He is also the Prime Minister's family physician. He is a New Zealander by birth, and in his student days at Edinburgh was well known as secretary of the Australasian Club.

Milsom Rees, C.V.O., F.R.C.S.Edin., Laryngologist to the King and Queen and also to Queen Alexandra.

Dr. Rai Kailash Basu Bahadur, C.I.E., a member of the Municipal Corporation of Calcutta.

C.M.G.

Surgeon-General Guy Carleton Jones, Director of Medical Services, Canadian Expeditionary Force.

C.B.

Temporary Surgeon-General Humphry Davy Rolleston, M.D., F.R.C.P., R.N., Consulting Physician to the Royal Naval Hospital, Haslar.

Lieutenant-Colonel William Westropp White, I.M.S. Fleet Surgeon Arthur Gaskell, R.N.

LEPROSY AND LEPER HOUSES.

THE history of leprosy in Great Britain—and, indeed, throughout Europe—forms one of the most remarkable chapters of epidemiology.

Monogram of Abbot Beere.

For several centuries it was so widespread and the cases so numerous that the disease seized on the public mind, leading on the one hand to a great dread of it, which caused the enforcement of restrictions on the leper which were often cruel, consigning him to a living death; and, on the other hand, to a great outburst of benevolence which sought to mitigate the misery of the sufferers in their isolation by establishing homes in which they could live in some sort of comfort. No doubt diagnosis was not always accurate, and cases of other chronic diseases, such as joint and gland tuberculosis, lupus,

and even psoriasis, may have been involved, but this does not explain the remarkable disappearance of the disease, rather it makes the explanation more difficult.

Dr. Mercier devoted his last course of FitzPatrick Lectures before the Royal College of Physicians of London to leper houses and mediaeval hospitals. He has published the two lectures in a pamphlet¹ which contains a great deal of information and some interesting discussion.

Leprosy existed in this country in Saxon times, and the oldest leper house, still existing as a charity, appears to be St. Oswald's Hospital at Worcester, founded by Bishop Oswald in 992. Dr. Mercier thinks, judging from the number of leper houses founded, that the disease reached its height in the second half of the twelfth century. In the first half of that century there were founded at least 46 hospitals, of which 24 were leper houses; in the following fifty years, at least 120, of which 56 were for lepers; in the thirteenth century, 240 hospitals, of which 75 were leper houses; and in the first half of the fourteenth century, 111, of which 42 were leper houses. In that century leprosy began to decline—a fact which Dr. Mercier associates with the Black Death, which swept the country in 1348-9. With the disappearance of leprosy the endowments of the leper houses either disappeared or were devoted to other charitable purposes. One of the oldest leper houses in England, the fabric of which still exists and is used for charitable purposes, is the Hospital of St. Margaret, Monkton, just outside Taunton on the London road. It is a long, low, narrow structure, consisting of seven distinct tenements, each with a staircase communicating with the room above; the walls are of stone, faced, for the most part, with plaster, and have a high-pitched thatched roof. The first and last tenements stand out in advance of the five middle ones, but the roof is

carried on continuously from one end to the other; the middle part is supported on thirteen wooden posts, rising from a parapet wall and thus forming a kind of cloister, out of which doors open to the several apartments now in use as almshouses. According to the researches of the Rev. Thomas Hugo, published in the *Proceedings* of the Somersetshire Archaeological and Natural History Society for 1871, the charity was probably established about the middle of the twelfth century, for it is mentioned in an undated charter which must have been granted between the years 1174 and 1185. During the second half of the thirteenth century it received endowments from Thomas Lambright. It was at that time a dependency of the Abbey of Taunton, which appointed the chaplain of the hospital; it appears always to have been a small and poor institution, and possibly for this reason it was permitted to continue its charitable work down to the dissolution of the monasteries. When it was burnt down, early in the sixteenth century, it was rebuilt by Richard Beere, Abbot of Glastonbury, who inserted in the front wall a panel with an escutcheon bearing his initials, surmounted by a bishop's mitre. During the reign of Henry VIII it was still called the Spital House, and in 1548 housed "vj poore lazare people." Apparently about this time all the property was confiscated and sold. Mr. Hugo finds no evidence that the almshouse itself was sold, and thinks it probable that, as was the case with the Hospital of St. John the Baptist at Bath, thanks to some powerful man in the neighbourhood, the old building continued without interruption to be devoted to its ancient use. Exactly when it became an almshouse does not appear to be known, but in 1612 an order was made regulating for the time to come the management of the almshouse, and a "governor of the house and family there" was appointed. Eventually some of its endowments appear to have been recovered, and are still available. Since 1612 the place has been uninterruptedly used as an almshouse. In 1750 there were six residents, and the number has usually been six or seven. It is stated that "the only advantage the inmates derive from the charity is that they live house-rent free, but they are all recipients of parish relief. As a *quid pro quo*, the overseers receive the rents of the various lands, amount-

ing at present to £45 10s., which rents are regularly credited in their yearly accounts passed by the union auditor, and go into the general fund in aid of the poor rates. The overseers out of their funds keep the 'Spital' in repair."

Another interesting example of the endowments of a leper house being diverted to other charitable purposes is afforded by the Magdalen School, Combe Down, Bristol, which, by an order made by the Charity Commissioners in 1891, enjoys the revenue

Old leper house at Taunton, Somerset, now an almshouse.

of the endowments of a leper hospital founded in the twelfth century by the Prior of Bath Abbey. The prior built a chapel, dedicated to St. Mary Magdalen, and also a hospital adjoining for lepers. In the sixteenth century it was used for "lunatics," and there is evidence that in the eighteenth century two or three idiots were kept in the hospital at the expense of the master. In the last century, when the new scheme was settled, the income was applied to the purposes of the institution for idiots.

The incomes of some of the mediaeval hospitals were considerable, derived chiefly from gifts of land. The diet given to the lepers was in some cases liberal; thus, at Shireburn Hospital in Yorkshire, for 65 lepers the daily allowance, Dr. Mercier states, was a loaf and a gallon of

¹ *Leper Houses and Mediaeval Hospitals*. London: H. K. Lewis. 1915. (Is. net.)

ale to each, with meat on three days in the week, and fish, cheese, or butter on the remaining four days. In addition, they had fire, candles, and all necessities.

Dr. Mercier dwells on the fact that tuberculosis seems in modern Europe to have replaced leprosy as the most serious of chronic infective diseases. He even goes so far as to put forward the hypothesis that the bacillus of leprosy has changed in the course of time into the bacillus of tubercle; the two, he says, are "so closely allied that if we hold at all the theory of evolution we must presume either that they own a common descent from some progenitor or that the one is evolved out of the other." He continues: "Thus the ancient leper house has not only its modern representative, but also its lineal descendant, in the modern sanatorium for consumption. In mediaeval times, every city and every burgh had its leper house. For all the triumphs of modern progress, modern science, modern sanitation, and modern care of the sick, we are still far behind our ancestors of six and seven hundred years ago in the provision of homes for the victims of the great scourge of Christendom."

MEDICAL CARE OF SCHOOL CHILDREN.

(Continued from p. 19.)

MOTHERS, BABIES, AND GIRLS.

IN the matter of schools for mothers there appears to be considerable danger of overlapping between the work of the Board of Education and the Local Government Board—the one being concerned directly with schools for mothers, and the other with maternity centres.

Tables are given showing the work of 157 schools for mothers; it would appear that the number of infants brought to the schools is not as yet very large. The return for 137 schools is 22,870, and the figures include children up to 5 years of age in several instances—that is, an average of 167 to each school. The average number of visits made with each infant varied in different schools from 2 to 19. Grants in aid made by the Board amounted in all to upwards of £6,100.

"Day nurseries" now number about 150; of these 80 applied for recognition, and received grants amounting to £5,100. The Board require as a condition of recognition a certificate from the medical officer of health to the effect that the institution is one which may suitably receive grants in aid.

"Nursery schools" have been founded by voluntary and independent efforts, and, as a rule, are intended to form a link between the home or the day nursery and the public elementary school, and are usually organized in general accordance with the recommendations of the Consultative Committee of the Board published in 1908. For the most part the ages of the children range from 3 to 5 years. The education given is largely a matter of practice in personal habits and conduct, of developing the brain, muscles, and senses, of teaching the beginnings of discipline and self-control. The general work of the schools can best be illustrated by a description of one of them. The Caldecott Community have had one in St. Pancras, London, since 1911. The school takes 57 children. The premises are specially furnished for the purpose. A bath-room, a cloak-room fitted with open wire boot holes, low wash-basins, a peg with a towel and toothbrush for each child, and a sleeping room furnished with stretcher beds, are provided. Two large classrooms are equipped with small tables and chairs and low wall blackboards. The daily time table is as follows:

- 9.0 to 9.30. Hats and coats removed. Washing. Teeth cleaning. Toys played with. Birds fed. Rooms dusted.
- 9.30. Prayers.
- 9.55. Cleanliness inspection.
- 10.0. Free occupations.
- 11.0. Lunch.
- 11.30. Singing games or free play. Gardens in summer.
- 12.0. School closes. Free play for those who stay dinner.
- 12.45. Dinner.
- 1.30. School reopens. Sleep for younger children. Free occupations for older children.
- 3.0. Children write diaries of day's work.
- 3.15. Closing exercises.
- 3.30. School closes.
- 4.0. Tea for those whose mothers are at work.
- 4.30 to 6.30. Play for those whose mothers are at work.

There is a routine medical examination of each child twice a year. There is a weekly meeting of a Mothers' Club, at which the mothers are encouraged to discuss the welfare of their children.

The teaching of mothercraft to girls in public elementary schools is making distinct advances. "Experience with schools for mothers shows that many women have had no instruction at all in infant care before their children were born, and that they have been dependent for advice on family traditions, and on hints given by neighbours and relatives. It is certain that infant mortality and suffering would be materially reduced if all women could have some training in the management of infants before or soon after marriage. If such apparently simple matters as the proper way to care for, to clothe, and to feed a healthy baby were known to them, they would without doubt be able to keep their infants in better health, and would be more ready to seek advice on the appearance of early signs of sickness." This instruction can be most generally given in school. "Girls of 12 to 14 years often take charge of their little brothers and sisters at home, and get some idea of the details of infant management." That practical experience makes them readily appreciative of teaching in school. Methods of washing, dressing, and clothing a child appeal to them, and practice in these details may lay the foundations of good treatment of their own children in later years.

Reports of the working of these classes show that they are essentially practical. At Swinton "a baby was procured for demonstration purposes when required, and each girl was given an infant to nurse, and become acquainted with the handling thereof whilst the demonstration proceeded."

UNCLEANLINESS.

Apart from the well-recognized conditions of physical defect that are to be met with in children, there are a number of disabilities that arise out of a general state of dirt and ill condition. It is even likely that this volume of physical unfitness is chiefly responsible for the incapacity of the child to take advantage of the education provided for it. Further, a dirty and ill-conditioned body is the easier prey to disease of all sorts. There is another side; any scheme of education that does not inculcate cleanliness as the first essential in the care of the primary capital of our youthful citizens is scarcely worth the name.

The routine medical inspections and the "systematic vermin surveys" conducted by the nurses in the schools show that there is still much room for improvement, particularly in the town children. The grand total for the conditions of the head of over a million children gives 81 per cent. clean, 17 per cent. nits only, and 1 per cent. with pediculi. The state of the body in the same children was a little better—85 per cent. were clean, 13 dirty, and in 1.2 lice were found. Approximately equal numbers of boys and girls were examined, and the comparison of the returns shows that dirty heads were 19 per cent. more frequent in the girls, and dirty bodies 7 per cent. more frequent in the boys. The long hair of the girls and the more permanent clothes of the boys probably account for the differences.

The towns are much worse than the counties. In London dirty heads total 21 per cent.; in the counties 9.5. In London, dirty bodies 21.4 per cent.; in the counties 3. Some of the difference is accounted for by the stricter methods of examination, and the higher standard of cleanliness held in London, but the fact remains that it is easier to be clean in the country than in the town. In combating this evil the "surprise" visits of the nurses play a valuable part, and have an advantage over the routine examinations of the doctors. The fact of inspection has a beneficial effect. On a finding of uncleanness notices requiring cleansing are sent to the parents. Compulsory cleansing is carried out when the condition is not remedied after notification. Prosecutions are made under the attendance by-laws of the authority, or under Sections 12 or 122 of the Children's Act, 1908, against parents who, after repeated warnings, have failed to keep their children clean.

Although the figures given show that there is ample room for improvement, it can be said with certainty that there is a very different view of lousiness in the minds of the people now than was current even a decade ago. Then it was a natural effect, "bred from the weakness of the child," now it is a disgrace to most, and but for the perpetual nuisance

of a few incorrigibly lazy parents it would be well nigh banished from the schools. A great part of the social disability attached to the public elementary school would vanish with the extinction of the louse, and the magisterial authority which treats lightly his final arbitrament over the case of a habitual offender does injury to the majority of wholesome and cleanly mothers and children. The parent is the real offender, and in this connexion it is of interest to note the report that the areas which have been most successful in combating this unpleasant and degrading condition are those which have instituted home visitations by school nurses or by members of Children's Care Committees.

MALNUTRITION.

"Something like 10 per cent. of the total number of children attending public elementary schools are suffering from malnutrition." The returns this year are founded on the examination of half a million children, and they confirm the findings of previous years. Malnutrition is not exactly a measurable quality; it is one that must rest on the considered and careful opinion of the school doctor. It is based upon the balance of several findings: Weight in relation to stature, the general balance and "substance" of the body, the firmness of the tissues, the state of the skin and mucous membranes, the tone of the controlling mechanism as shown by listlessness or alertness.

A most interesting schedule of the returns obtained during the medical inspection is given for counties, county boroughs, boroughs and urban districts. The results show that, excepting London, the degree of malnutrition (below normal and bad) is lowest in the rural areas. In London the comparatively good record is credited to "the activities of the numerous organizations which exist in the area for the preservation and protection of the public health, and to the social machinery concerned in the amelioration of insanitary conditions arising out of uncleanness and overcrowding." Probably some of it is due to the Friday and Saturday night coster markets.

The returns tend to show that more boys than girls suffer from malnutrition. This is possibly accounted for by the fact that there are more boys than girls engaged in some form of employment outside school hours.

School nurses and care committees have followed up children found to be defective and made inquiries into the conditions of their home life. The result has been in the main an insistent witness to the close connexion which exists between malnutrition and (1) unsuitable food, (2) enlarged tonsils and adenoids and tuberculosis, and (3) insufficiency of sleep.

Many medical officers speak of the importance of the food factor. Dr. Orr (Shrewsbury) writes: "The women of the working-classes often show a surprising ignorance of the proper methods of cooking for family requirements; a want of knowledge of the value and suitability of food-stuffs." He debits the responsibility to our educational methods, and claims a place in making up this deficiency for the schools for mothers, where instruction is received "with the greatest enthusiasm and interest by the women." Dr. Macdonald (Northampton) says:

Another potent factor in the production of chronic dyspepsia, which is, I believe, much more common amongst children than is generally thought, is the all-pervading antiseptic preservative. This is not restricted by any means to tinned products, but in the form of boric acid, formalin, salicylic acid, and so on, haunts our fresh butter, milk, cream, and other comestibles.

The London reports state that in one form or another tuberculosis is a cause of malnutrition in over 25 per cent. of the cases where any cause is assigned, and the parents are urged by the Care Committee to attend the local tuberculosis dispensary or other institution where treatment can be obtained. Dr. Roberts (Denbighshire) states that—

Insufficiency of sleep is another cause which unquestionably has a deleterious effect upon the growth and healthy development of the school child. One feels that the evil habit of late hours is becoming more general. Children of tender years who should be in bed crowd the poisoned atmosphere of the picture-dromes, and before long it will become essential to make regulations controlling the admission of children to such shows, as the question is becoming one of vital importance.

Besides all these points there are certain conditions associated with growth that have to be taken into account. Dr. Hamer (London) reports: "There is no doubt a seasonal influence; thus it is known that in spring children

remain almost stationary in weight while they increase in height, and it is therefore probable that any particular group examined in the spring term would show an excessive degree of malnutrition, just as nervous disorders, such as chorea, are more prevalent in this season of the year. Again, there is an age factor. During certain years growth in height is much more rapid than in the years that precede or follow, and many observers have noted the tendency to loss of energy and tone at these periods of growth. In a study of the causation of malnutrition made last year it was shown that rapid growth was confined to the leaver group as amongst school children."

The main contributions of the authorities to the cure of this condition appear to be the provision of regular and adequate meals, and in this one factor probably lies the great benefit of the open-air schools.

Tables are given showing the degree of nutrition in school children as revealed in the course of medical inspection in the areas of sixty-two local educational authorities. Some of the returns are distinctly perplexing. For example, one would have thought that a rural area like the county of the Isle of Wight would have presented a good record for fine plump children, but the returns are worse than for London; indeed, the percentage of children judged to suffer from bad nutrition is the second highest on the list, being 2.2 per cent. This is in strange conflict with another return from the same island county, which gives the incidence of cases of phthisis and other forms of tuberculosis as very low, the figures falling within the lowest group. Cases of conflicting returns such as these are not infrequent; they are probably susceptible of easy explanation, such as variation in the standard of judgement; but it would appear well worth the while of the Board to inquire as to their meaning.

(To be continued.)

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on December 14th, 1915, 46 cases were considered, and £448 granted to 40 of the applicants. The following is a summary of the cases relieved:

Widow, aged 41, of L.R.C.P. Edin. who practised at Edmonton, and died in 1910. At husband's death applicant was left practically unprovided for, with two children now aged 8 and 10 years. Has managed to earn a living until the war commenced by literary work. Has friends in Los Angeles who recommend her to go there, as the prospects look good for herself and children. Help required towards her passage, etc. The Fund granted £20, and the Guild also provided clothes. The Professional Classes War Relief Council co-operated with the Fund and made a grant of £10.

Daughter, aged 27, of L.R.C.P. Irel. who practised in Ireland, and died in 1895. Applicant's health was undermined through the long nursing of her mother who has recently died. The Fund made a small grant a little time ago to enable her to take a short holiday. A further grant of £2 was made.

Widow, aged 45, of M.R.C.S. Eng. who practised at Gravesend, and died in January, 1915. Applicant was left with three daughters, aged 13 to 21, and one son, aged 20, who is abroad and whose health has broken down. Applicant required a little help towards the education of the daughters to earn their own living. Owing to the war it was impossible to sell the practice to advantage at present. Applicant voted £10 and the case referred to the Guild with a view of helping with the education of the girls.

Daughters, aged 62 and twins 45, of M.D. Edin. who practised in London, and died in 1873. Applicants' immediate trouble caused by the death of mother who had a life interest in some property. They endeavour to make a living by taking in paying guests and doing needlework, but have not been very successful of late. Voted £10 and referred to the Guild.

Daughter, aged 44, of M.R.C.S. Eng. who practised in South Wales, and died in 1872. She was brought up by friends and when able to work managed to earn a living as a laundress, but recently has developed cancer which has quite incapacitated her from working. Voted £12 in twelve instalments, and referred to the Guild.

Widow, aged 45, of M.R.C.S. Eng. who practised at Beccles, where he had only recently established himself, and died in January, 1915. Applicant is trying to earn a living by taking in paying guests, but owing to some extent to her house being near the East Coast, she has not been very successful, but has prospects of improvement. Voted £10.

Daughter, aged 58, of M.D. Dub. who practised in the Isle of Man, and died in 1882. Applicant's money was badly invested, and she lost all; she is now an invalid suffering from rheumatoid arthritis. She is highly recommended by the Liverpool branch of the Guild. Voted £5 through the Liverpool branch of the Guild.

(To be continued.)

British Medical Journal.

SATURDAY, JANUARY 8TH, 1916.

ENROLMENT.

THE publication of Lord Derby's report has intensified the general interest taken in his scheme of attestation, and members of the medical profession who have not followed the relation of the profession to a scheme which may prove to have paved the way for a compulsory military service will desire to know as precisely as possible the present position as it is viewed by the Central Medical War Committee. That Committee is in close conference with the Medical Department of the army, and has now worked out the whole system of recruiting of officers for the R.A.M.C.

The Central Medical War Committee is at present completing a list of all medical men of military age (that is to say, all of 45 years of age or under) who have not yet received commissions. It fully recognizes the need for taking into consideration local and individual difficulties, and is in communication with the local Medical War Committees who are preparing lists of medical men of military age for each area, classified according to the scheme published in the SUPPLEMENT to the JOURNAL of December 11th, 1915, p. 214. As these local lists are completed a communication will be addressed to each medical practitioner of military age asking him to fill up a form, giving his name, age, qualifications and other personal particulars, and another form authorizing the Central Medical War Committee to forward to the War Office his application for a temporary commission R.A.M.C. so soon as in the opinion of that Committee the time has arrived when his services should be placed at the disposal of the military authorities, the Committee on its part undertaking to give him at least one month's notice. On receipt of this form of application for a commission the Committee will at once send him a certificate of enrolment, stating that the application has been received and is duly registered with the Committee. This form of enrolment is equivalent to attestation under the Derby scheme. The scheme of the Committee applies only to men who are willing to give their whole time, and it is assumed that every fit man will be prepared to make this sacrifice.

It should be clearly understood that the application of the individual practitioner for a commission, which, according to the scheme, will be in the hands of the Central Medical War Committee, will not be sent in until all his circumstances have been fully considered. This consideration will include the individual's responsibilities with regard to persons dependent upon him, and to partners, institutions, or public authorities. With regard to the general interests of the country it will include the proportion which medical men who remain in practice in the area bears to the needs of the general population, and every means will be taken to equalize the call throughout the country.

It is not possible to mention any number as the total of medical men who will be required by the army within a stated time; this must depend partly upon the development of military operations and

partly upon the amount of wastage among medical men already serving in the army. The understanding is that when the Army Medical Department needs more medical officers it will state the number required to the Central Medical War Committee; that Committee will then inspect the whole list of enrolled men and will select those who, from the information in the possession of the local Medical War Committees and the general information as to the whole country in the possession of the Central Medical War Committee, can be withdrawn from civil practice with least disadvantage to the public, to their brother practitioners, and to themselves.

As has been observed on previous occasions, there are residential areas where the proportion of medical men in civil practice is very much higher than in industrial districts, and it is certain that further calls must be made upon men practising in such areas. The public must understand that the conditions under which they have been accustomed in time of peace to obtain the attendance of their medical men cannot continue without modification; customs which have long prevailed in residential districts must be modified. In cases of sudden serious illness it will, of course, still be necessary to send for the doctor, but a great deal of his time could be saved without loss to the patient if well-to-do people who can get about easily would form the habit of going to see their doctor instead of requiring him to go and see them. Moreover, the amount of time commonly involved in paying a visit to a house may be materially curtailed without any real loss to the patient and with great saving of the doctor's time. On the other hand, it should be clearly understood that the scheme under which doctors are now invited to enrol with the Committee presents very great advantages from their point of view; they will engage under the conditions which have prevailed since the beginning of the war, that is to say, the commission they promise to accept will be for a year, at the end of which time they will be able to review the position. If the opportunity is lost and compulsion has to be faced, it is possible that the whole medical profession will be practically converted into a State service; compulsion on the individual will not then be limited in time, but he will be required to serve at least for the duration of the war. Thus it is of the utmost importance that every medical man of military age should sign the application submitted to him. Those who hold back are not unlikely to bring the whole of their medical brethren within measurable distance of a form of compulsion disastrous to the profession.

A Commission appointed at the instance of the Ministry of Munitions to inquire into labour conditions in the munitions factories of France has reported among its conclusions that the people of France realize that they are at war, and that the one idea in the mind of all is to bring the war to a successful issue. The result of their mission, they state, has been to convince them that the increase of the production of munitions in France is due to one cause, and one cause only, and that is the patriotic enthusiasm which exists there. These are not the conclusions of doctrinaires, but of practical men—among others, the chairman of the Amalgamated Society of Engineers and the secretary of the Engineering Employers' Federation.

Some light is thrown on the question how far the people of this country realize that they are at war by Lord Derby's report on the result of his effort as Director-General of Recruiting, published as a white paper on January 4th; it consisted of three parts, but

the first and third parts only are published, the second having been put out of date by the great influx during the last few days on which enlistment under the group system was open. The first part, giving a general account of the scheme and what was done under it, has, Lord Derby states, the unanimous assent of his colleagues on the Joint Committee, formed of the Parliamentary Recruiting Committee and the Joint Labour Recruiting Committee; but for the third and more objective part, which involves a number of calculations and the estimate of deductions which must be made, Lord Derby is responsible, although in the compilation of the statistics he has had the assistance of Dr. T. H. C. Stevenson, Superintendent of Statistics at the General Register Office. From the crude total figures for the period from October 11th, when Lord Derby was appointed, to December 15th, it appears that 2,950,514 men came forward and either attested in groups or enlisted immediately into the army; the latter numbered rather over a quarter of a million, but of the large total nearly half a million (428,853) have already been definitely rejected on medical grounds. For comparison we may quote the figures for Australia given in a recent telegram to the *Times*, from which it appears that of the 1,224,162 males between the ages 18 and 60 registered in Australia, 775,419 (63.34 per cent.) have been classed as fit, 380,232 (31.06 per cent.) as doubtful, and 68,511 (5.6 per cent.) as unfit. The number of fit men between the ages of 18 and 34 is 422,814.

It is stated that of the remainder who have attested in this country nearly a million (925,445) have not yet been medically examined. In the analysis of the single men and married men attested, the deduction made for the number of men likely to be found unfit on medical examination is 40 per cent. This is one reason why Lord Derby says that the figures on analysis do not prove as satisfactory as could have been wished. His general conclusion is that there are 651,160 unstarred single men unaccounted for in Great Britain.

The bill to make provision with respect to military service in connexion with the present war, introduced by the Prime Minister on January 5th, follows the general lines of Lord Derby's scheme, but introduces the principle of compulsion in respect of unmarried men and widowers without children dependent upon them. The voluntary attestation system, however, remains open, and though, under the scheme outlined above, it does not directly affect medical men, it may be well to add, with regard to the working of the local and central tribunals under it, that all claims sent to the local tribunal are forwarded at once to the recruiting officer or the military representative, who has the assistance of an advisory committee. The grounds on which the application is made are shown in the claim, which is considered by the military representative in consultation with his advisory committee. Necessary inquiries into the accuracy of the statements set out by the claimant are made, and if the committee and the military representative are satisfied that the claim is reasonable, it is agreed to and returned to the local tribunal, and in this case no formal proceedings take place before that tribunal, the claimant being simply informed that his claim has been assented to. Should the advisory committee and the military representative after inquiry consider that the claim is one which requires to be dealt with judicially by the local tribunal—that is, by a hearing of the claimant and of other necessary witnesses—the claim is sent to the local tribunal to be so dealt with. The advisory committee will not require the claimant

to appear before it, as that committee is not a court, but there is no objection to its interviewing a claimant who wishes to attend in order that he may informally explain his case to the committee. There is an appeal to the central body set up under the authority of Lord Lansdowne's committee. The bill proposes to continue the local tribunal, though it is not certain that the advisory committee will be continued, and also the central appeal body, but it introduces an intermediate appeal tribunal nominated by the Government for areas larger than those covered by the local tribunal.

INFANT LIFE PRESERVATION.

THERE is abundant evidence that the public is at last beginning to view with anxiety the enormous wastage of infant life and to realize that a considerable proportion of this loss is preventable. The subject has been discussed by writers in the medical press in all countries, but especially in this country, in France, and in America, for the last ten or twelve years, until the facts and figures have become very familiar to the medical profession. Through it the public has become interested, and in England, Scotland, and Ireland lay organizations exist which are endeavouring with more or less success to force the question on public attention. Infant consultations have been established in many centres throughout the country, particularly in the large towns, and the good effects of their system of regular medical inspection and weighing of infants, and of the education of mothers by informal "health talks" and home visiting, have been apparent in the improvement of the infant mortality-rate before the war. That so much success has been achieved is a standing testimonial to voluntary effort, but grants have also been forthcoming from the Board of Education, from the Local Government Board, and, in some instances, from the local municipal authorities.

These efforts following on the awakening of the public conscience may be abortive if the municipal authorities are not alive to their responsibilities in this direction. In many localities medical officers of health have met voluntary workers half way, and have used their influence to enlist the support of the local authority; in others—notably, we understand, in some of the poorest and most crowded districts—their attitude has been far from sympathetic. The work is too important and too urgent to be subjected to such vicissitudes of fortune. It has never been more urgent than at present. Out of every 800,000 children born alive we lose approximately 114,000 in the first year of life; to this must be added the number of infants lost by death of the fetus during the forty weeks of antenatal life, estimated by Dr. Newsholme as 138,249 during 1914 in England and Wales.

With such figures before us, it does not seem too much to hope that the favour with which infant welfare and maternity centres are regarded by the Government will be better reflected by the legislature. Further, though under the Notification of Births Act the names and addresses of the mothers of the babies are available, full advantage cannot be taken of this knowledge without the co-operation of the medical officers of health. Maternity or infant welfare centres should know from what source or sources they can confidently expect a grant or grants to cover their expenses, provided that they attain a certain definite standard of efficiency. At present this point is often obscure, for three bodies are implicated—the Board of Education, the Local

Government Board, and the local municipal authority. The support of the latter is often problematical, and if obtained, being temporary, is unstable. The management committees of the centres, although the work done may be consistently good, feel that their prospects of continuing from one year to another is altogether on the knees of the gods.

The establishment of crèches for the babies of those mothers who go out to work is germane to the subject. Many such crèches are already in existence, and an appeal was made recently for one which it was proposed to establish in Notting Hill for the babies of mothers who are engaged on Government contracts. It is proposed that the crèche shall be established near the homes of the mothers. Such an undertaking deserves encouragement, and may be the best that can be devised in the present emergency, but it is open to question whether its value would not be enhanced if it were situated near to the mothers' place of work rather than to their homes. In judicious breast-feeding lies the key to the prevention of many infant deaths. If the crèche be situated close to the factory, the baby can receive a breast-feed during the dinner hour, and, with a little ingenuity, arrangements could be made whereby artificial feeding might be unnecessary; on the other hand, if the mothers leave their infants in a crèche near their own homes and go out to work for the day, artificial feeding, with its attendant dangers and disabilities, is a necessary consequence. The appeal states that "a project is on foot to form after the war a permanent crèche on a much larger scale." Such a statement evokes two criticisms apart from that already expressed. In the first place, the establishment of crèches is not one of those many projects which can profitably be deferred until after the war. The need will never be more pressing than it is to-day. The other criticism concerns the advisability of forming "large" crèches. One of the arguments which, with some reason, has often been urged against these institutions is that they are liable to become potent centres for the dissemination, not only of exanthemata, but of other epidemic disorders of infancy. With large crèches this danger would be increasingly difficult to control. Again, a large crèche, unless it be situated within or near a large factory, implies that many babies will unnecessarily be deprived of human milk.

BRITISH RED CROSS WORK.

WHEN war broke out there were two national organizations for bringing voluntary help to wounded and sick soldiers and sailors—the British Red Cross Society and the St. John Ambulance Association. The latter was one of the principal departments in the Order of St. John of Jerusalem in England, and had established the St. John Ambulance Brigade, which had done excellent work in South Africa, and also in civil life. The British Red Cross Society, which had been preceded by the National Aid Society, was incorporated in 1908, with King Edward VII as patron. It received the official recognition of the Admiralty and War Office as the organization responsible for the Red Cross movement throughout the Empire; at the same time, both the Admiralty and the War Office agreed that in time of war they would receive voluntary offers of assistance made in Great Britain and Ireland only through the society, except those in respect of the supply of personnel from the St. John Ambulance and the St. Andrew's Ambulance Association. The main

object of the British Red Cross Society was then defined to be the examination, systemization, and co-ordination of all offers of help, so that, by the prevention of waste and overlapping, they should be given their greatest possible value.

The similarity of the work proposed to be done by the British Red Cross Society and the St. John Ambulance Association caused certain risk of overlapping and led apparently to some little friction. A War Office Committee was therefore appointed to inquire into the relations between the two organizations, and held its first meeting in July, 1914. When, however, the war began to make urgent calls upon the energies of both, a shorter way was found, and an amicable arrangement was reached which took effect from October 20th, 1914. The joint War Committee of the two bodies was formed with the Honourable Arthur Stanley, M.P., of the British Red Cross Society, as chairman, and Sir H. C. Perrott, Bt., of the Order of St. John, as vice-chairman, while Sir Frederick Treves of the former society and Mr. Edmund Owen of the latter made themselves responsible for the selection of personnel and many other matters which fall to be decided on medical authority. The co-operation immediately commanded the approval of the public, as is shown by the fact that during the first year of the joint working of the two organizations donations of the public amounted to £1,864,036.

The Joint Finance Committee of the two bodies, of which Sir Robert Hudson is chairman, has recently issued a very full statement of accounts for the year ending October 20th, 1915. The Joint Committee, in addition to what it has done in respect of the transport of wounded, has maintained or helped hospitals in France and Flanders, in Malta, and the Near East, in Africa, and in England. The total sum expended during the year was £1,642,271 6s. 5d., leaving balances in hand amounting to £221,764 17s. 7d. The use of the plural is due to the fact that about half the contributions received were ear-marked by the donors for particular classes of work, and in particular to the fund for the transport of wounded, to which more than half a million was contributed. The Finance Committee pleads that its work would be simplified if a larger proportion of the donations were sent to the general fund, since, while some of the special funds have considerable unused balances, others have had to be heavily supplemented from the general fund.

The largest single item of expenditure is for the transport of wounded. Large as was the sum contributed to it, this fund was overdrawn to the amount of nearly £62,000. The overdraft is attributed to the fact that, in order to secure delivery when wanted, it was necessary to place orders for motor ambulance cars many months ahead. The coal owners and coal workers have undertaken to supply the whole of the overdraft, and indeed much more, for the work of the motor convoys. The sum expended on the purchase of motor ambulances was £446,400, and the cost of working and maintaining them was £169,562. By far the greater part of the fleet has been working in France and Flanders, but cars were maintained also in Egypt, Malta, Serbia, Italy, and Great Britain. The number of ambulance cars is 897, but the total number of cars in use is raised to 1,245 by the repair wagons necessary, and by lorries, soup kitchens, and touring cars; in addition there are 56 motor cycles. The Committee has also two ambulance launches, three petrol ambulance launches, and an iron lighter punt working in the Mediterranean, three petrol ambulance launches working in the Persian Gulf, and

a steamer of 150 tons used for carrying Red Cross stores from Alexandria to the Dardanelles. This steamer and the three petrol launches used in the Mediterranean were presented to the Committee, which has had, however, to bear the cost of alterations and upkeep. The four hospital trains cost in round figures £44,000; one of these was converted at the cost of £4,000; the average cost of the other three was about £13,000. It should be added that the whole of the capital outlay on motor ambulances, hospital equipment, trains, etc., has been charged against the income of the year.

The value of the goods purchased or given during the year was £463,455 11s. 4d. The estimated value of goods in kind represent 43 per cent., and the majority were received in comparatively small quantities, and had to be unpacked, sorted, sized, and repacked. The fact that the management expenses only amounted to 2.96 per cent. of the value of the stores handled was due in part to the number of voluntary helpers. The joint management expenses estimated on the whole fund amounted to 2½d. in £, or if the cost of appeals be added, to 3½d. in the £. This is due again partly to the number of voluntary workers and partly to the fact that owing to the generosity of the Royal Automobile Club and Lord Michelham, the expenditure on rents, rates, etc., did not amount to £25. Heavy expenditure has been entailed by the establishment and maintenance of the St. John Hospital at Étapes, the British Red Cross Hospital at Netley, and the King George Hospital in London. Contributions have also been made to the base hospital at Nairobi, and the Cameroons Field Hospital for the wounded of the North-eastern Rhodesian Field Force, and to the Anglo-Russian Hospital, as well as for the benefit of sailors and soldiers who have been crippled or blinded.

PROPOSED COLLEGE OF NURSING.

THE Hon. Arthur Stanley, M.P., who has been acting as the chairman of a committee of matrons and managers of some London hospitals, has addressed a letter to hospital committees containing a proposal for the establishment of a college of nursing, to regulate the courses of study and technical training for nurses and to form an examination board. Mr. Stanley states that during his year's work as chairman of the Joint War Committee of the British Red Cross Society and the Order of St. John he has been struck by the lack of organization amongst the various authorities responsible for the training of nurses, and by the need for organization among the nurses themselves. He observes that the more or less active agitation which has been going on for something like twenty-five years in favour of the registration of trained nurses has hitherto failed to attain the object sought. Assuming that something should be done at once to co-ordinate the various interests involved, he thinks that without prejudice to ultimate developments, whether by legislation or otherwise, it will be necessary to rely, for the time at least, upon a voluntary scheme of co-operation among the nurse-training schools throughout the country. The college he proposes would be a purely voluntary body, which would aim at securing the support and sympathy of the governors of hospitals to which nurse-training schools are attached, of the matrons and lecturers at these nurse-training schools, of the leading members of the medical profession, and of the trained nurses themselves. For the promoters of the college he would look to persons belonging to the several classes enumerated, and he suggests that, having obtained the sanction of the Board of Trade to the registration of the college with its memorandum and articles of association, they should appoint the first

council of management, two-thirds of whom should be matrons of hospitals or superintendents of nursing. For effective administration this council must, he considers, be small, and it is proposed therefore that it should form a large consultative board, drawn from all classes of nurse-training schools and nursing associations, and from nurses in practice throughout the country, and that the council should always invite and receive a report from this consultative board before coming to a determination either upon courses of study and technical training, or upon the conditions under which recognition should be extended to nurses' schools. It should also form an examination board to advise upon the appointment of examiners, the scheme for examinations, and the acceptance, under safeguards, of internal examinations in recognized training schools to qualify for the certificate of proficiency in nursing which would be granted by the college. The college should also take power, it is suggested, to exercise similar functions in all branches of women's work connected with hospitals, whether naval, military, or civil, and to give certificates of proficiency to those who pass the necessary examinations. Mr. Stanley adds that he has reason to hope that, should these proposals meet with sympathetic support, he may be able to secure financial assistance to launch the college in a suitable building. He invites the committee of each hospital addressed to nominate representatives to take part in the establishment and development of the college.

PROFESSOR METCHNIKOFF ON DEATH.

PROFESSOR ÉLIE METCHNIKOFF of the Pasteur Institute at Paris celebrated his seventieth birthday last May. The occasion was marked by quiet commemoration and the reunion of friends, while the professor himself, with characteristic spirit, delivered an address¹ on the subject of "Death." As he pointed out, the age of seventy was generally recognized as the natural limit of normal life. In his own family death came earlier, and he attributed his survival to the hygienic regimen by which he lived. As is well known, Professor Metchnikoff holds that the normal bacterial flora of the alimentary tract is actively harmful to man, and he proposes to secure longevity by abstention from uncooked food, and the sedulous cultivation of relatively harmless microbes, notably those of the lactic acid fermentation of milk, in the intestine. He calls for the study of "scientific macrobiotics," or the science of long life, suggesting that it should be begun on the inhabitants of homes for the aged. When the problems of rational macrobiotics are better understood, the professor expects to see a keener desire to live manifested by old people, for they will then arrive at old age with their faculties less impaired than is at present usually the case. In a later contribution² to thanatology, the science of death, Professor Metchnikoff examines the causes that lead the imago of *Bombyx mori*, the Southern European silkworm moth, to die a natural death after but two or three weeks of life. This is a moth without the suctorial apparatus necessary for feeding, and so it lives and dies without taking food. Its digestive tract is incapable of ingesting or absorbing nutriment; indeed, it is a poor thing that serves only for the ejection of a drop of transparent alkaline fluid that softens the cocoon and permits the moth to escape. Hence the imago would appear to be designed for a short life only, and its death should therefore be a truly natural death in most cases. Professor Metchnikoff, having reached this general conclusion, proceeded to investigate the actual causes of death in a number of cases. The stomach and tissues were found to be sterile in three-quarters of 115 silkworm moths examined after natural death; the remainder showed infection with diplococci or moulds that may well have been the immediate cause of death. May not some

¹ Ann. Inst. Pasteur, Paris, 1915, xxix, 364

² Ibid., 477.

invisible filterable virus have been present in the apparently sterile majority, and the cause of their death? To this question no definite answer can be given at present, for want of adequate means of investigation; the professor leaves it open, and attaches some importance to its solution. Is mere starvation to be set down as the cause of death? Apparently not, for the bodies of the moths always contain after death a quantity of unused fat, even when life has been unusually prolonged; this residual fat is less in the females than the males, being exhausted by ovulation, yet the females live a little longer than the males as a rule. Is death caused by some exhaustion of the muscular or nervous tissue, such as may be demonstrated under the microscope? No, for the muscle fibres preserve their normal histological structure after death, the nerve cells present no abnormal pigmentation or vacuolation; it has been noted that some of the tissues—for example, the heart and the spermatozoa—may survive the natural death of the moth for many hours. Finally, uraemia and anuria come up for consideration; does the normal silkworm moth succumb to an anuric toxæmia? No, once more. Micturition is always observed soon after the moth has left the cocoon, and may be repeated for a day or two, or even after a week or more in exceptional cases, but anuria during the greater part of life is the rule. Yet this anuria depends only on suppression of micturition, and the bladder is found after death to be distended with fluid and uratic deposits; the moth's Malpighian tubules are active during life. This urine is undoubtedly highly toxic to silkworms, silkworm moths, and mice, on subcutaneous injection. Hence Professor Metchnikoff is unable to exclude uraemia as a cause of the natural death of these moths, although he is far from asserting that the one is the cause of the other; the question is one demanding further investigation on the lines of pathological chemistry. He entirely disagrees with Marinisco's attribution of old age and death to dehydration of the colloids in the tissues, which is, indeed, an admirable example of the *obscurum per obscurius* to which men of science are so unfortunately prone. And he is inclined to believe with Bloch that death in human beings is never natural, properly speaking, but is always precipitated by the intrusion of some avoidable factor, whether from within or from without. For himself, Professor Metchnikoff tells us, he regards intestinal infection as the most redoubtable of these factors, and he adds that for eighteen years he has done his best to neutralize its injurious effects by due attention to his intestinal flora. We wish him all possible success in the long continuance of his efforts in this direction!

VACCINE THERAPY IN ENTERIC FEVER.

Using the vaccine employed prophylactically in the Italian army, Dr. A. Fagioli has recently recorded¹ a small number of cases of enteric fever in which the disease has been cut short and has ended by crisis after the intravenous injection of from 100 to 300 million of the bacteria, the dose for prophylactic purposes being 400 million. No details as to the method of preparation of this vaccine are given, but Dr. Fagioli sees no reason for believing that an autogenous vaccine would give better results. He has never seen any harm result from the use of the intravenous method of administration; the injection is followed in a few minutes, or at any rate within an hour, by a rigor and a sharp rise of temperature to 105° or 106° F. The temperature falls eight or nine degrees within twenty-four hours, with profuse diaphoresis, and the patient becomes convalescent. The best dose of antityphoid vaccine to give can only be determined empirically; Dr. Fagioli began with 150 million bacteria, but found that with this amount a second injection a few days later might be necessitated by a recrudescence of the fever, and he now prefers to give

up to 300 million bacteria. He has not met with any case of cardiac failure or arrhythmia as a result of the treatment, or with any unpleasant symptoms that could be attributed to it. For the rest, the patients are treated on the general lines that ordinarily obtain. A case of paratyphoid B fever is quoted in which the antityphoid vaccine (200 million) produced an equally satisfactory and rapid cure on the eighteenth day of the disease; and a case of typhoid fever of severe type cured by the intravenous injection of 100 million *B. coli* vaccine on the twentieth day. No explanation of these anomalous cures is offered; the author notes that in two of the cases of typhoid fever treated successfully the characteristic leucopenia was replaced by a slight leucocytosis a few days after the injection. Dr. Fagioli has had some success in the treatment of Malta fever and tuberculosis of the lungs by intravenous injections of starch, a substance he supposes to act by developing anaphylotoxins. He gives 5 c.cm. or 10 c.cm. of a 5 per cent. solution of Kahlbaum's starch, and he quotes two cases of enteric fever in which a series of four such injections appeared to shorten the course of the disease. Some light on the question how injections of antityphoid vaccine may cut short enteric fever is thrown by Dr. F. P. Gay, who notes² that the treatment of enteric patients with a modified sensitized antityphoid vaccine produces a specific leucocytosis, mainly polymorphonuclear, the count rising as high as 20,000 or 40,000 white cells per cubic millimetre. In addition, he finds that the treatment develops a high agglutinating power in the patient's serum, no doubt an index of the development of some substance antagonistic to the *Bacillus typhosus*. The dose of vaccine he advocates contains about 300 million bacteria.

ETHER ANAESTHESIA.

In the BRITISH MEDICAL JOURNAL of May 29th, 1915 (p. 939), the question of priority in the introduction of ether anaesthesia into surgical practice was discussed, and the claim advanced on behalf of Dr. Crawford Williamson Long was admitted. At the same time it was pointed out that it was William Thomas Green Morton who compelled the attention of the medical world to the value of ether as an anaesthetic, and that to him, therefore, belongs the glory of the discovery. An interesting note on Long appeared in the *Journal of the American Medical Association* of October 30th, 1915, in which it is stated that Dr. Allen J. Smith has recently published in facsimile the documentary evidence relating to his work. Altogether, says our contemporary, there are eleven pages of photographic reproductions of letters and attestations of various kinds, including Long's statement of account with James Venable, from the back of whose neck he removed one of two small wens under ether on March 30th, 1842. The understanding was that if this operation was painless the other growth should be dealt with in the same way. This was done on June 6th, a fact which implies that the ether had been successful on the former occasion. It has been suggested, by ourselves as well as by others, that Long did not appreciate the importance of his discovery. The documents published by Dr. Allen J. Smith, however, prove that he continued to use ether, although he failed to convince his professional brethren of its value. Mr. George Foy, of Dublin, writes to point out that the centenary of Long's birth fell on November 4th. Mr. Foy also quotes an unpublished letter written by Long to his friend Dr. L. A. Dugas, Augusta, Ga., in which he states that his mind had early been directed to the fact that persons while etherized were insensible to pain from falls and injuries. Long's grandfather emigrated from the neighbourhood of Letterkenny, not far from Sligo, the birthplace of William Higgins, who predicted that the ethyl series of alkyls would furnish an anaesthetic.

NERVE DEAFNESS AND MUMPS.

ATTENTION is drawn by Dr. Hubbard¹ to the fact that nerve deafness after mumps is by no means so rare as perusal of the current textbooks would lead the reader to imagine. Mumps is given as the cause of nerve deafness in from 3 to 5 per cent. of deaf-mutes. Dr. Hubbard states that there are about 50,000 deaf-mutes in the United States of America, of whom perhaps 2,000 owe their disability to mumps. In fact, mumps ranks close to scarlatina as a cause of absolute bilateral deafness, and probably the percentage due to mumps is still higher where unilateral nerve deafness is considered. The subject is, therefore, one of no little clinical and social importance. It is disappointing to find that the pathological anatomy of this form of deafness has been little studied; it is vaguely attributed to labyrinthitis, and the labyrinthitis is set down as a metastatic infection with the microbial virus of mumps, which may well be the virus described by Dr. M. H. Gordon² as capable of passing through a Berkefeld filter, and as the cause of acute lymphocytic meningitis when injected into the monkey. Others hold that ear trouble in mumps is due to the extension of the inflammatory process along the Eustachian tube. Be that as it may, auditory symptoms may occur at any stage of mumps, even before the parotid swelling appears; they consist of tinnitus, variable degrees of deafness, vertigo, nausea, vomiting, disturbances of equilibration, and headache. Naturally the cases vary very widely in severity; in some there remains no more than a slight impairment of the hearing, in others there are islands of tone perception in certain registers, while in yet others there may be complete deafness in one or both ears. In Dr. Hubbard's own cases he noted that the destruction of both cochlear and vestibular nerve functions might be complete or partial, making possible some degree of restoration of function. He draws the important practical conclusion that the evil effects of the labyrinthitis are due to the fact that there is no room for inflammatory products within the rigid labyrinthine cage; increased tension of the endolymph and perilymph rapidly injures and destroys such delicately balanced structures as the organ of Corti, the thin membranous partitions, and the terminal vestibular fibres. He regards the present treatment of the aural complications of mumps as unsatisfactory, and suggests that lumbar puncture should be given a trial, because lowering of the subarachnoid tension may lower the tension of the perilymph. Alternatively, Dr. Hubbard calls for a method of applying modern surgical decompression to the labyrinth capsule—an operation, one would say, demanding no little delicacy of touch on the part of the operating surgeon.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.

THE current issue of the *New English Dictionary* (a single section) carries the alphabetical rubrics from *Subterranously* to *Sullen*, and has been under the immediate care of Mr. C. T. Onions, one of the three lexicographers who now, since the death of Sir James Murray, edit this great work, national in nature if not in name. The first medical or rather semi-medical term met with in this instalment is *subventaneous*, with its meaning of "windy," and its application to conceptions and to eggs. "*Subventaneous eggs*," wrote Holme in his *Armoury* (1688), "are such as the Hen brings forth without the Treading of the Cock," and some forty years earlier Sir Thomas Browne had referred in his *Vulgar Errors* to "the Mares in Spaine and their subventaneous conceptions from the western wind." One does not think of *subversion* as in any sense a medical term, but once upon a time (Mr. Onions tells) *subversion of the stomach* signified nausea, and Crooke in his *Body of Man* (1615) wrote of "the great

consent between the stomacke and the kidneyes, and the subversion of the stomacke and frequent vomits." The verb *subvert* was also used in the sense of to upset the stomach (as one would say now), and Venner (in 1620) warned the readers of his *Via Recta* against "the sweet Orengees which are not fit for sauce, because they subvert the appetite, and cause loathsomnesse in the stomacke." The anatomical term *subvertebral* and the embryological *subzonal* are both faithfully entered and correctly defined, and the latter is illustrated by two quotations from Sir William Turner's work on *Human Anatomy* (1877). Most interesting paragraphs are devoted to *succedaneal*, *succedaneous*, and *succedaneum*, meaning acting as a substitute and a substitute. In the seventeenth century medicinal applications and ingredients were called *succedaneous*, as in the illustrative quotation, (of 1657) which declares that "by succedaneous secrets the same diseases may be restored, although not with the same speed or universality." *Succedaneum*, the noun, has the special medical significance of "a drug, frequently of inferior efficacy, substituted for another"; and one remembers that the practice of using succedanea is obsolete at the present time, although "substitution" is not unknown. One of the illustrative quotations is from Fuller (famed for his *Worthies* and his wit) and reads: "Physicians have their Succedanea, or Seconds, which well supply the place of such Simples, which the patient cannot procure." The obstetrician will, perhaps, find fault with the makers of the *New English Dictionary* for not including his often-employed term *caput succedaneum* either here or under *caput*, but they will possibly put up the plea of non-naturalization. Among the quotations Carlyle's famous phrase, which has again some added significance in these days, is not omitted: "Paper, which in many ways is the succedaneum of gold." The obstetrician possibly will again grumble because Mr. Onions has not referred to the *succenturiate* placenta (so troublesome sometimes and so elusive), especially as he has made mention of the suprarenal capsules as the "*succenturiate kidneys*," a much less frequent use of the word. A number of medical terms appear under *succin*, including *succinic*, *succinite*, *succinol*, and *succinyl*, and *succus* is not forgotten. Special uses of *sucking* are exhaustively catalogued, even the *sucking pads*, the lobulated masses of fat occupying the space between the masseter and the buccinator muscles, being named and defined. "*Sudden stroke*," too, a synonym of apoplexy, is not missed. Other medical words are *sudamina*, *sudoral*, *sudoresis*, *sudoriferous*, *sudorific*, *sudoriparous*, *sufflation*, *suffumigation*, *suggilation*, *sulculus*, and *sulcus*; and the medical usage of *suffer*, *sufferer*, *suggest*, and *suggestion* is carefully recorded. Apart from its medical aspects, the *Dictionary* is no less complete.

A MEDICAL OFFICER VINDICATED.

THE Walsall and West Bromwich Unions Joint Committee and other related bodies have an institution at Great Barr Park. It at present accommodates about 100 children and the staff, but buildings are now nearing completion for about 250 mental patients. Miss Anna Sinclair was appointed matron of Great Barr Hall on August 9th, 1912, and it had been proposed to appoint a resident medical superintendent and an assistant medical officer, but, owing to the war, these appointments were deferred, and Dr. W. Maule Smith was appointed non-resident medical superintendent in October, 1914, and commenced his duties on January 1st, 1915. On October 12th, 1915, the committee interviewed Miss Sinclair, and afterwards directed its clerk to inform her that unless she sent in her resignation her appointment would be terminated. The resignation was not received, and on October 21st notice to terminate the appointment was given to Miss Sinclair. On November 1st Miss Sinclair sent a letter to each member of the committee making grave charges and general allegations against Dr. Maule Smith, and asking

¹ T. Hubbard, *Trans. Amer. Otological Soc.*, xiii, Part 3. New Bedford, Mass., 1915.

² BRITISH MEDICAL JOURNAL, 1914, i, p. 1413.

for an investigation at the meeting of the committee on the following day. The committee unanimously decided to ask the Local Government Board to hold an inquiry. The Board instructed the committee to hold the investigation itself. After some correspondence with Miss Sinclair's solicitor, Mr. Durby, the committee permitted him to appear on her behalf at the inquiry, and to make a statement in her absence. Dr. Smith was present at the inquiry, and was represented by Mr. W. E. Hempson. The proceedings extended over three days, and eleven witnesses were heard. The committee has furnished us with a report of its investigation, in which the charges against Dr. Smith are set out, and the findings of the committee thereon stated. It suffices for us to say that the committee's report states as follows: "We have no hesitation in entirely exonerating Dr. Smith from all the charges and insinuations made against him by Miss Sinclair." We desire to offer our congratulations to Dr. Maule Smith and the Medical Defence Union, on whose instructions Mr. Hempson represented him, upon this complete vindication of his professional honour and reputation.

RAILWAYS IN WAR.

NAPOLEON, a man who had the virtue of knowing his own mind and not hesitating to express it, said he preferred a dead soldier to a wounded one. How far would he have modified this unsympathetic attitude of mind if he had had all our modern railways and railway ambulance transport to serve his ambitions? The question is one that is discussed very fully, though indirectly, in a book Mr. Edwin A. Pratt¹ has published recently. He gives a most interesting historical account of the influence of railways in the conduct of warfare. Great Britain is a country devoid of strategical railways; our iron roads were built to serve commerce only. Germany, on the other hand, was already busy building "aggressive" railway lines aiming at France and Russia as long ago as 1842; with what success it is needless to point out now. These, however, are matters that do not directly concern us; but Mr. Pratt has a most interesting chapter on railway ambulance transport—a branch of railway work that has grown out of all knowledge since its crude beginnings in the Crimean war sixty years ago. The hospital train, it appears, was invented in the American War of Secession, 1861-65, and attained so high a degree of efficiency during the last eighteen months of that war as to be of high strategical as well as humanitarian value. Thus we are told that the provisions made for the wounded during this period were worth an army of 100,000 men to the Federal forces. Each train consisted of five ward cars, a surgeon's car, a dispensary car, an ordinary passenger car for the less serious cases to sit in, a kitchen car with dining-room and storeroom, and a conductor's car. The trains had distinguishing signals which were recognized by the Confederates, and none of them were ever fired on or molested in any way. *O si sic omnes!* Some of these cars were specially built for the purposes they served. They were warmed and lighted in winter, and special attention was devoted to their ventilation. Mr. Pratt gives an interesting account of the use made of hospital trains in the chief wars of the last fifty years, and of their steady improvement in design and effectiveness. Their most recent representatives have been on view in London, Edinburgh, and other large towns during the past year, and have been visited and admired by many of us who are non-combatants. The bulk of Mr. Pratt's book is occupied with the economic and strategic aspects of railway development all the world over. It is well written and well documented, and should be welcome to the many readers of the daily papers who are in process of becoming well-grounded students of politics at home and abroad.

¹ *The Rise of Rail-Power in War and Conquest, 1839-1914.* By E. A. Pratt; with a Bibliography. London: P. S. King and Son, Ltd. 1915. (Demy 8vo, pp. 417. 7s. 6d. net.)

SCIENCE AND ADVERTISING.

No sooner is a discovery made in medicine than it is greedily seized upon by enterprising "providers" as a text upon which to preach their wares, until, like an operatic air that has been adapted to the barrel organ, it soon becomes unspeakably hackneyed. What tons of paper have been printed over to the tune of Garrod's discovery of uric acid, to push the sale of preventives, solvents, and destroyers of that peccant substance, which is now recognized to be an incidental and comparatively harmless by-product of gouty proclivities! Ever since Lister made public his immortal discovery we have been overwhelmed with antiseptics—antiseptic drugs, antiseptic dressings, antiseptic garments—in fact, almost everything one can think of except antiseptic babies. Then came the era of intestinal antiseptics, "warranted to cure" in spite of the asseverations of physiological chemists of repute, who denied the possibility of a successful direct attack on hypothetical microbes in a canal lined by exquisitely sensitive cells. Metchnikoff introduced the conception of phagocytosis, and forthwith came a procession of drugs, ointments, and lotions to promote, facilitate, and, if need be, compel, leucocytes *qua* phagocytes to do their duty. Huchard, or some other inventive genius, suggested "demineralization of the tissues" as the underlying cause of weakened resistance to microbial attack, and lo! phosphates, hypophosphites, and glycerophosphates flooded the market, the fact being ignored that a spendthrift who is unable to keep his money in his pocket is unlikely to succeed in retaining money conferred upon him as a gift. Investigators have ascribed beri-beri and rickets, pellagra and scurvy to the absence of hypothetical substances in prepared and preserved foods. Every patent food worth mentioning is warranted to contain a surfeit of vitamins. Well might the cynical French professor exclaim, "Make haste to use the new remedy while yet it cures."

Medical Notes in Parliament.

War.

Naval and Military War Pensions Committee.—The Prime Minister on January 4th stated that the Prince of Wales had consented to act as chairman of the statutory committee set up by the Naval and Military War Pensions Act, and that the paid vice-chairman would be Mr. Cyril Jackson. The other members of the committee are as follows:

Major-General Sir Ivor Herbert, Bt., C.B., C.M.G., M.P.; Mr. A. A. Allen, M.P.; Sir Henry Craik, K.C.B., M.P.; Mr. C. J. Mathew; Sir W. Ryland Adkins, M.P.; Lord Chylesmore, K.C.V.O.; the Right Hon. G. N. Barnes, M.P.; Mr. H. Gosling; Mrs. Sidney Webb; Miss Durham.

Sir Nominees of the Royal Patriotic Corporation: The Right Hon. W. Hayes Fisher, M.P.; Admiral Sir Wilmot H. Fawkes, G.C.B., K.C.V.O.; Mr. B. B. Cubitt; Mr. J. E. Rayner; the Countess Roberts; Mrs. McKenna.

Two Nominees of the Soldiers' and Sailors' Families Association: Lieutenant-Colonel Sir Donald Robertson, K.C.S.I.; the Countess of March.

Nominees of Government Offices: Treasury, Mr. H. E. Haward; Admiralty, Mr. C. M. Bruce; War Office, Lieutenant-General the Hon. Sir F. W. Stopford, K.C.M.G., K.C.V.O., C.B.; National Health Commissioners, Mr. D. J. Shackleton; Local Government Board, Sir S. B. Provis, K.C.B.; Local Government Board (Scotland), Sir R. Macleod, K.C.B.; Local Government Board (Ireland), Mr. C. H. O'Connor.

Men Temporarily Unfit.—Mr. Partington, on January 4th, asked whether, in view of the shortage of labour, men returned from active service and temporarily unfit for further service were allowed to return to civil life. Mr. Tennant said that men who are medically unfit for service abroad or at home, and who are not likely to become fit within six months, are discharged from the service; but men who are temporarily unfit are not discharged. He recognized the necessity of returning to civil life men no longer fit for military service, but it was necessary that the permanent unfitness should be conclusively established.

THE WAR.

WAR NEPHRITIS.

At a meeting of the K.k. Gesellschaft der Aerzte¹ in Vienna the etiology of the serious outbreaks of nephritis which have occurred among soldiers was discussed by, among others, Professor A. Klein and Dr. Pulay. Their investigations had been carried out in the First Reserve Hospital and in the Serotherapeutic Institute in Vienna. A large number of cases of haemorrhagic nephritis observed in April and May were attributed to a variety of different causes, such as sore throats, slight undetected scarlatina, and "chills." It was also frequently suggested that inoculation against typhoid fever might have been responsible. The clinical picture was fairly uniform: slight fever and oedema, accompanied by headache and tiredness. The urine contained albumin and blood and casts of every shape. Polyuria, nocturnal incontinence, and signs of pyelitis, including leucocytes and mucus in the urine, were observed in many cases. In 25 *B. coli* was found in pure culture in the urine, and yet these micro-organisms were very seldom found in the urethra. It was suggested that the bacilli might have reached the kidneys by the lymphatic system or the blood, the bladder having escaped infection. It was further assumed that the thermal and mechanical conditions to which soldiers were exposed facilitated the migration of the *B. coli* from the intestine to the kidneys, particularly if there was some lesion of the intestine, and in many cases the subjects of nephritis had previously suffered from dysentery, enteritis, or typhoid fever. In this connexion great interest attached to the frequency with which jaundice had lately been observed among soldiers who had previously contracted dysentery or enteritis. In many diagnosed as cholecystitis following "coli sepsis" the distended gall bladder was palpable. It was considered too early to attempt to formulate a definite prognosis in these cases of haemorrhagic nephritis; but on the whole a benign course was anticipated. Only three cases had terminated fatally, and in them probably the disease was of old standing. In one case the large white kidney was found, and in two cases the small, granular kidney (*Schrumpf-niere*). The symptoms in these three cases were those of sepsis, not those of uraemia. The necropsy also showed signs of sepsis, including enlargement of the spleen. The flooding of the urine with *B. coli* was intermittent, whereas haematuria was the most persistent phenomenon. It was considered advisable to keep the patients under observation for some time after they had apparently recovered. In a great number of the cases there was a definite relation between previous attacks of intestinal disease and pyelonephritis. It was maintained that this condition was far more common than was generally recognized, and that the *B. coli* played an important part in its causation.

In his contribution to the discussion Professor H. Schlesinger pointed out that the frequency with which the nephritis occurred in March and April suggested one common cause. He had been told by some army surgeons that the nephritis, in a certain number of cases, had been intentionally provoked by such drugs as cantharides and chromic acid, but this explanation probably held good only for a negligible proportion of all the cases. The nephritis was characterized by the length of the acute stage and by the obstinacy with which symptoms persisted. The haematuria often lasted many months. It was a curious fact that in a great number of cases hypertrophy of the heart did not supervene. He was somewhat sceptical as to the relation between intestinal disease and nephritis. He was of the opinion that the subjects of haemorrhagic nephritis were no longer fit for active service.

Professor Strasser said that he had seen about one hundred cases of "war nephritis." The severe symptoms were, in his opinion, evidence of extensive renal disease. He had often found as much as 3 per cent. albumin in the urine. About twenty of his cases belonged to the category of "coli sepsis." There were, however, many cases the etiology of which was independent of the *B. coli*. There must be many soldiers on active service whose kidneys

had previously been injured by scarlatina or other disease, and also, assuredly, alcoholists, whose reaction to cold and overwork would take the form of renal disease. Discussing the hypothetical relation between intestinal disease and nephritis, he drew attention to the facts that, though the epidemic of dysentery had culminated in September and October, the maximum incidence of the nephritis was observed more than half a year later. In very many of his cases the patients had been exposed to wet and cold, which, as experience proved, must provoke albuminuria. He had found nothing to check the haemorrhage in these cases. Though he considered soldiers who had recovered from this nephritis no longer fit for active service, he thought they might still be used for less strenuous military duties. On active service such patients were liable to relapse.

Dr. A. Schiff insisted that many of these patients had been treated for nephritis before the war, and that their "war nephritis" was nothing more than a relapse. In six out of seventeen cases the patients attributed their symptoms directly to exposure to cold. He also drew attention to the fact that, though the epidemic of dysentery had ceased, cases of nephritis in the field were still cropping up. Indeed, soldiers who had not been on active service sometimes developed nephritis after exposure to cold. He thought that with proper treatment many of these patients would recover; but in view of the frequency with which relapses occurred he considered they should not be sent back on active service. In two of his cases he had traced the nephritis to a previous attack of dysentery.

Professor E. Schwarz expressed his astonishment at the frequency with which nephritis occurred; he remarked that though pyelonephritis was well known in time of peace, haemorrhagic nephritis was exceedingly rare. Though he did not deny the part played by micro-organisms, he thought that in many cases the outbreak of the disease was determined by exposure to cold. He had found both polyuria and oliguria among his patients, and he thought these phenomena might represent different stages of the same disease. The last traces of albumin and blood were difficult to banish from the urine, and were apt to increase again on provocation, such as over-indulgence in alcohol. Another speaker confessed that the severe haematuria observed in some of these cases was unaffected by dietetic and therapeutic measures. Many of his patients had never suffered from any intestinal disease. Professor K. Landsteiner reported that he had found the paratyphoid bacillus in a case of parenchymatous nephritis associated with numerous haemorrhages. Professor L. Braun confirmed the statement that this nephritis was not confined to soldiers returning from the front, but was also observed among soldiers remaining in Vienna. He did not think that the nephritis could be traced to one common cause, and he had observed cases in which no explanation of the origin of the disease was forthcoming; the examination of the stools was negative, there was no sign of dysentery, and the patients had not previously been exposed to a soaking.

Professor C. Singer, on the other hand, considered that dysentery in many cases was a predisposing factor, and called to mind that dysentery might be followed by septic infection. Protective inoculation might well lead to the stirring up of quiescent micro-organisms. Among many patients suffering from jaundice there was a history of paratyphoid infection, and agglutination of the paratyphoid bacillus was often observed in these cases. Dr. Pribram cited experiments on animals to show that the subcutaneous injection of immune bodies even in large quantities did not harm parenchymatous organs.

MALINGERING IN THE FRENCH ARMY.

(From a Correspondent.)

From various recent communications in the French medical press it is plain that the problem of outwitting the malingerer is one which occupies a large share of the army surgeon's attention. It is equally plain that the simulation of different diseases has become a fine art, though the ingenuity displayed in this direction is often wasted owing to the simulator's ignorance of pathological associations and limitations. There have been epidemics of jaundice which for some time greatly puzzled the medical officers

of hospitals at or near the front, but the very number of the cases led to close inquiry, when it was discovered that a yellow coloration of the skin can be brought about by the ingestion of picric acid. Once suspicion was aroused the unmasking of the perpetrator was an easy matter and a court-martial followed. The directions for the detection of picric acid in the urine are to render it alkaline and add a solution of potassium cyanide (1 in 5). On heating, the mixture yields a deep purplish-blue tint. Another test is to shake up a sample of the urine with twice its volume of ether, whereupon the latter acquires a yellow hue. If a strip of white wool be steeped therein it is dyed yellow and the colour cannot be removed by washing. If the dyed wool is dipped in a solution of ammonium sulphide, it turns red. Apart from these chemical tests, the jaundiced subjects do not present the colourless stools, slowness of pulse, or itching associated with jaundice, and the urine does not contain bile pigments.

Another popular trick is to introduce white of egg into the urine or even to inject it into the bladder; it renders the urine albuminous, in diminishing quantities, for twenty-four hours. As a rule simulators overstep the mark in that the amount of albumin is incompatible with the general health of the subject. A modification of this trick is to have a little white of egg in a pocket, the finger is dipped into it when the man is asked to micturate, and the jet is made to wash the albumin off into the specimen for examination.

In another series of cases oedema is simulated by injecting water beneath the skin, and in the same order of ideas we meet with fixation abscesses determined by the injection of paraffin or turpentine. The former causes a mild abscess, but the inflammation set up by the latter may be serious. These abscesses are usually situated on the inner aspect of the left lower limb, and the patient describes himself as suffering from "phlebitis." It follows that phlebitis of the left leg, starting on the inner aspect, should be regarded with some suspicion. The points to be borne in mind in arriving at a diagnosis are that the area of inflammation is strictly localized, and develops around the mark of a puncture; there is no tendency to lymphangitis and no rise of temperature or constitutional disturbance. Care must be taken in opening these abscesses not to apply iodine, ether, or other odoriferous substance to the skin because this might prevent the characteristic odour of paraffin or turpentine being perceived on evacuation. There is, however, no limit to the misplaced ingenuity of the pacifists in this direction. Victims of slight wounds to the head have been known to prolong their convalescence indefinitely by provoking inequality of the pupils by the judicious use of atropine. Some men on their way to the front are taken ill, and have to be detained at a station infirmary, the favourite device being acute conjunctivitis, induced by means of snuff or powdered ipecacuanha, or facial "erisipelas" precipitated by the application of croton oil. Hydrarthrosis of the knee is simulated by placing a potato in the popliteal space and strongly flexing the joint for a few hours, just as swelling of the feet can be brought about by tying the puttees too tightly. Simulated epilepsy is a form of deceit that will not withstand close scrutiny, and men suspected of "trying it on" are at once sent to the line of fire *pour encourager les autres*. There have been many cases of alleged retention or incontinence of urine consequent upon nervous shock, but careful observation and instrumental exploration enables the specialist to decide which cases call for treatment and which may safely be ignored. The detection of simulated defects of sight and hearing calls for highly technical methods of investigation which have now been so perfected that probably not even the specialist himself could steer his way through the maze and escape conviction.

EXPERIENCES OF A NORWEGIAN DOCTOR IN AUSTRIA.

A NORWEGIAN doctor, Einar Aaser, who served for several months with the Austrian forces in various districts, has published an account of his experiences in *Norsk Tidsskrift for Militærmedicin* (vol. xix, No. 3, 1915).

FAULTY AMBULANCE ORGANIZATION.

In the early months of the war the transport of the sick and wounded from the front was hopelessly disorganized,

and many of the sick spent over a week on the railway on their way to the base hospitals. Even when the infectious nature of disease was recognized at the front the patients were crowded together with the wounded, and were hurried inland without isolation precautions. The injunction not to use the lavatories while a train was halted at a station was a dead letter to patients suffering from cholera, dysentery, and typhoid fever, and among the civilian patients infection was frequently traceable to neglected disease among the soldiers. Indeed, at one time in Vienna there were more civilians than soldiers suffering from dysentery. Dr. Aaser suggests that this disease among civilians might have been largely averted had the military authorities adopted measures to protect civilians as well as soldiers from infectious disease. In war time the non-military authorities found themselves practically powerless to cope with the problems of infectious disease among the civil population.

FEEDING THE WOUNDED AT RAILWAY STATIONS.

According to the mobilization scheme, the train service was slowed down, the maximum speed being 17 kilometres an hour. Journeys, therefore, which under ordinary conditions would have lasted only a day, took three to four. At the few stations where refreshment stalls existed the arrival of a train was a signal for a free fight for sausages and beer. Matters were considerably improved when the Red Cross organized refreshment stalls free of charge at the large stations, where the military trains usually stopped for some time. The ladies who volunteered for this service met the trains at all hours of the day and night, and supplied with food and drinks not only the sick and wounded returning from the front, but also the new drafts travelling in the opposite direction. In spite of the admirable services rendered by these ladies, the system was abandoned, probably because of the fear of infection.

DYSENTERY.

Soon after the outbreak of the war the Wilhelmina Children's Hospital in Vienna was set aside for the treatment of men suffering from dysentery. Before admission to the pavilions of the hospital they were rubbed with parasitic applications to destroy lice. Most of the soldiers referred the onset of the disease to attacks of anorexia, rheumatic pains, and slight rigors. Only a few had suffered from vomiting. These prodromal symptoms were soon followed by almost continuous pain in the epigastrium, accompanied by severe diarrhoea and almost unbearable tenesmus. Though the evacuations were often as frequent as thirty to forty a day, and prevented sleep, the general appearance of the patients was, on the whole, good; and it was very exceptional to find cyanosis, collapse, and other signs of severe infection. The soldiers complained of having had to march for as long as five days at a time out of touch with the commissariat, and on these occasions they had to subsist on the potatoes they dug up and the fruit they picked. The supply of water was also inadequate. Though the majority of the men in one company was infected, only a few gave up; the rest struggled on, and when a certain district had been left behind the outbreak ceased suddenly. This was attributed to the escape from an area saturated with infection by soldiers defaecating on the march. The treatment was principally dietetic; a full fluid diet was combined with narcotics, such as morphine. Only the most severe cases were treated with serum, and its effects were scarcely noticeable. The results obtained by dietetic treatment in one hospital, by serum in another, and by intestinal irrigation in a third, were all good, and in the hospital in which Dr. Aaser worked there was only one death. In his opinion the subjects of dysentery recover in spite of every treatment.

CHOLERA.

After numerous outbreaks of cholera had occurred in different parts of the interior, the authorities realized how faulty the isolation of infected persons had been, and proceeded to establish large quarantine stations. Dr. Aaser was attached to one of these in Marisch-Weiskirchen, where 2,400 beds were provided, and where the wounded from West Galicia were detained for five to six days before being transferred to the interior. Subsequently he was transferred to Witkowitz, a manufacturing town only a few miles from Cracow. He estimates that the number

of cases of cholera in this area did not exceed a couple of thousand, and he was astonished to find how mild a course the disease usually ran. At the outbreak of the war no soldier had been inoculated against cholera, but after the disease had broken out in the Serbian campaign inoculation was made compulsory for every soldier; 1 c.cm. of an emulsion of dead cholera bacilli was injected subcutaneously, and the same dose was repeated four to six days later. The reactions were so slight that they did not interfere with the soldiers' duties. It was, in Dr. Aaser's opinion, this prophylactic inoculation which reduced the incidence of the disease and caused it to run so mild a course. When it attacked the uninoculated, its manifestations were much more alarming. The slight cases required little treatment apart from careful nursing; the severe cases were treated with calomel, charcoal, and bolus alba, given internally; and by subcutaneous injection of serum, the action of which, in many cases, was strikingly beneficial. Large subcutaneous or intravenous injections of saline solution were given as a last resource, and were often very effective. When hypertonic saline solution was used, it was given intravenously only. The mortality was very low, and only three out of about fifty patients died under Dr. Aaser's care. Though he attributed this low death-rate to prophylactic inoculation, he anticipated that this procedure was calculated to produce many slight cases and "carriers," who would be a source of grave danger to the uninoculated population when the soldiers returned home.

QUARANTINE ARRANGEMENTS.

The number of sick and wounded in a train which had been dispatched was notified to the quarantine hospital, and the whole staff met the train at the station and at once began to sort out the infectious from the non-infectious cases. Two non-commissioned officers collected the soldiers' weapons and equipment, and uniforms were at once disinfected in steam and subsequently washed. Meanwhile two elderly Sisters took charge of and registered the soldiers' money and other articles of value. The men were then bathed and put into clean clothing, and at this stage a further grouping was made, according as the cases were medical or surgical. As soon as the dressings were changed, the first meal, consisting of sausages, soup, and bread, was given. In a draft of men from the front, 10 to 15 per cent. usually consisted of infectious cases, but the nature of the infection was, as a rule, not recognized till the patients had been in quarantine for a few days. A great drawback to the system was the lack of facilities for operating in the quarantine station itself, and on several occasions it was necessary to ignore the quarantine and to transfer the patient to a purely surgical ward so as to perform some urgent operation. There were no fully-trained nurses available in this quarantine establishment, and the nursing devolved on women whose qualification for the work consisted of a three weeks' course of theoretical and practical instruction. Yet, on the whole, they did excellent service, not so much in changing dressings and handing instruments, as in helping the patients at their meals, writing letters for them, etc.

LORD FRENCH'S DISPATCH.

The following are among the names mentioned in Field-Marshal Lord French's dispatch of November 30th, 1915, for gallant and distinguished service in the field:

ARMY MEDICAL SERVICE.

General Head Quarters Staff, Etc.

Surgeon-Generals: W. G. Macpherson, C.B., C.M.G., M.B., K.H.P.; T. J. O'Donnell, D.S.O.; M. W. O'Keefe, C.B., M.D.; R. Porter, M.B.; F. H. Treherne, C.M.G., F.R.C.S.E.; T. P. Woodhouse, C.B.

Colonels: G. H. Barefoot, C.M.G.; E. G. Browne; C. H. Burchaell, C.M.G., M.B.; G. Cree, C.M.G.; R. H. Firth, F.R.C.S.; M. P. C. Holt, C.B., D.S.O.; G. D. Hunter, D.S.O.; R. Kirkpatrick, C.M.G., M.D.; S. MacDonald, M.B.; R. L. R. MacLeod, M.B.; C. E. Nichol, D.S.O., M.B.; D. M. O'Callaghan; W. W. Pike, D.S.O., F.R.C.S.I., A.M.S.; G. T. Rawnsley; J. J. Russell, M.B.; B. H. Scott; B. M. Skinner, M.V.O.; W. H. Starr; H. N. Thompson, D.S.O., M.B., A.M.S.; H. C. Thurston, C.M.G.; T. du B. White, M.B., A.M.S.; J. B. Wilson, M.D., A.M.B.; C. A. Young, A.M.S.

Temporary Colonels: J. Atkins, M.B., F.R.C.S., A.M.S.; W. C. Beevor, C.M.G., M.B., T.F. (Lieutenant-Colonel, *ret. pay*).

Lieutenant-Colonels: E. T. F. Birrell, C.M.G., M.B., R.A.M.C.; F. J. Brakenridge, R.A.M.C.; A. Chopping, R.A.M.C.; S. L. Cummins, C.M.G., M.D., R.A.M.C.; H. E. M. Douglas, V.C., D.S.O., R.A.M.C.; H. B. Fawcett, C.M.G., M.B., R.A.M.C.; L. N. Lloyd, D.S.O., R.A.M.C.; C. K. Morgan, M.B., R.A.M.C.; F. S. Penny, M.B., R.A.M.C.; H. S. Roch, R.A.M.C.; J. M. Sloan, D.S.O., M.B., R.A.M.C.; N. Tyacke (temp. Col.), M.B., R.A.M.C.

Majors: C. G. Browne, D.S.O., R.A.M.C.; B. B. Burke, R.A.M.C.; J. M. H. Conway, F.R.C.S.I., R.A.M.C.; P. Davidson, D.S.O., M.B., R.A.M.C.; P. G. Easton, R.A.M.C.; C. C. Fleming, D.S.O., M.B. (Res. of Off.); J. A. Hartigan, M.B., R.A.M.C.; T. E. Harty, R.A.M.C.; P. H. Henderson, M.B., R.A.M.C.; H. C. Hildreth, F.R.C.S. Edin., R.A.M.C.; J. D. Richmond, M.D., R.A.M.C.; M. B. H. Ritchie, M.B., R.A.M.C.; A. B. Smallman, M.D., R.A.M.C.; R. N. Woodley, R.A.M.C.

Captains: J. J. H. Beckett, R.A.M.C.; F. W. M. Cunningham, M.D., R.A.M.C.; R. Gale, D.S.O., M.B., R.A.M.C.; F. D. G. Howell, R.A.M.C.; W. P. MacArthur, M.D., F.R.C.P.I., R.A.M.C.; J. W. L. Scott, M.B., R.A.M.C.

Consultants.

Temporary Colonels: Sir B. E. Dawson, K.C.V.O., M.D. (Captain London General Hospital, R.A.M.C.T.F.); H. McI. W. Gray, M.D., F.R.C.S. Edin. (Major Scottish General Hospital, R.A.M.C.T.F.); W. T. Lister, M.B., F.R.C.S.; H. A. Thomson, M.D., F.R.C.S. (Captain Scottish General Hospital, R.A.M.C.T.F.); C. S. Wallace.

Royal Army Medical Corps.

Lieutenant-Colonels: L. Addams-Williams; J. E. Brogden; T. H. M. Clarke, C.M.G., D.S.O., M.B.; R. W. Clements, M.B.; V. J. Crawford, D.S.O.; G. H. Goddard; H. A. Hinge (temporary Colonel); A. W. Hooper, D.S.O.; W. E. Hudleston; E. T. Inkson, V.C.; F. Kiddle, M.B.; J. W. Langstaff; J. W. Leake; J. R. McMunn; C. W. Mainprize; E. W. P. V. Marriott; H. G. Martin; G. A. Moore, M.D.; W. H. S. Nickerson, V.C., M.B.; H. H. Norman, M.B.; M. MacG. Rattray, M.B.; J. P. Silver, M.B.; F. Smith, D.S.O. (Brevet Colonel); A. A. Watson (S.R.), (Lieutenant-Colonel R.A.M.C.T.F.); A. O. B. Wroughton.

Temporary Lieutenant-Colonel: T. C. English, M.B., F.R.C.S. (Captain London General Hospital, R.A.M.C.T.F.).

Majors: R. B. Ainsworth; E. G. Anthonisz; R. B. Black, M.B. (Res. of Off.); G. H. J. Brown, M.B.; J. H. Campbell, M.B.; K. A. C. Doig; Fitzg. G. Fitzgerald; A. W. Gibson; F. J. Hanafin; D. L. Harding, F.R.C.S.I.; H. Harding, M.B.; A. E. S. Irvine; E. F. Q. L'Estrange; R. P. Lewis; S. E. Lewis, M.B.; N. Low; J. T. McEntire, M.B.; A. A. Meaden; S. M. W. Meadows; A. H. McN. Mitchell; J. S. Pascoe; L. M. Purser, M.B.; J. M. B. Rahilly, M.B.; W. Riach, M.D.; T. F. Ritchie, M.B.; F. E. Roberts; E. Ryan; F. C. Sampson, M.B.; H. F. Shea, M.B.; M. Sinclair, M.B.; R. S. Smyth, M.D.; H. Stewart, M.B.; R. Storrs; R. J. C. Thompson; J. A. Turnbull; C. H. Turner; W. J. Waters; J. W. West, M.B.; R. K. White; W. Wiley, M.B.

Temporary Major: E. L. Gowland, M.B.

Captains: J. Adams, M.B. (S.R.); J. E. Allan, M.B. (S.R.); R. R. G. Atkins, M.B. (S.R.); J. H. Baird, M.B. (S.R.); D. C. G. Ballingall, M.B.; H. C. Bazett, M.B., F.R.C.S. (S.R.); W. K. Beaman; F. A. Bearn, M.B. (S.R.); E. C. Beddows; W. J. E. Bell, D.S.O., M.B.; J. E. Black, M.B. (S.R.); J. E. M. Boyd; A. B. H. Bridges; W. K. Campbell, M.B. (S.R.); A. G. W. Compton (S.R.); A. R. Dale (S.R.); E. C. Deane (killed); G. De La Cour, M.B.; R. M. Dickson, M.B.; M. G. Dill, M.D.; J. S. Dockrill, M.B. (S.R.); J. C. A. Dowse, M.B. (S.R.); A. C. Elliott, M.B.; E. J. Elliot, M.B.; P. Elvery, G.M.; D. (London Field Ambulance); G. White (London Sanitary Company); H. F. Wilkin, F.R.C.S. Edin.; G. S. Williamson (South Midland Field Ambulance); W. L. R. Wood.

Surgeon-Captain: R. W. Branthwaite (T.F.R.).

Temporary Captains: J. W. Craven, M.B. (Northumbrian Field Ambulance); J. H. Fletcher, R.A.M.C.; J. R. Marrack, M.B., R.A.M.C.

Lieutenant: S. R. Foster, M.B. (North Midland Field Ambulance).

INDIAN MEDICAL SERVICE.

Colonel: B. B. Grayfoot, M.D.

Lieutenant-Colonels: A. E. Berry, M.B.; J. A. Hamilton, M.B., F.R.C.S. Edin.; A. J. MacNab, F.R.C.S.

Majors: H. Boulton, M.B.; R. J. Bradley, M.B.; G. Browne, M.D.; H. M. Cruddas; A. N. Fleming, M.B., F.R.C.S. Edin.; J. Good, M.B.; C. Hudson, D.S.O., F.R.C.S. Edin.; W. W. Jendwine, M.D.; G. C. L. Kearns; R. A. Needham, M.B.

Captains: F. B. Shettle; H. S. Carmack, M.B., F.R.C.S. Edin.; V. B. Green-Armytage; S. H. Middleton-West, M.B.; R. B. Nicholson; W. C. Paton, M.B.; J. Scott, M.B.; J. Smalley, M.B.; C. H. Smith, M.D., F.R.C.S.; V. N. Whitmore; C. A. Wood, M.B.

INDIAN SUBORDINATE MEDICAL DEPARTMENT.

Bal-Mukand, No. 991 1st Class Sub-Assistant Surgeon; Hiralal, No. 1255 1st Class Sub-Assistant Surgeon P.; Hira Sing, No. 929 1st Class Sub-Assistant Surgeon, Rai Bahadur; Jassudassam, No. 1286 1st Class Sub-Assistant Surgeon S.; Kishan Singh, No. 1046 1st Class Sub-Assistant Surgeon; McMillan, 1st Class Assistant Surgeon W. C.; Maine, 1st Class Assistant Surgeon W. J. S.; Pohlo Ram, 772 1st Class Sub-Assistant Surgeon; Shaikh Hussain Ali, Subadar and 1st Class Senior Sub-Assistant Surgeon; Bishan Singh, 1143 1st Class Sub-Assistant Surgeon; Browne, 2nd Class Assistant Surgeon R. F.; Culpankum Virasami Rajagopal Pillai, 2nd Class Sub-Assistant Surgeon; Kishan Singh, 1246 2nd Class Sub-Assistant Surgeon; Pargan Singh, 1230 2nd Class Sub-Assistant Surgeon; Boilard, 3rd Class Assistant Surgeon E. H.; Mathurapershad Sarawit, 1360 3rd Class Sub-Assistant Surgeon; Messinier, 3rd Class Assistant Surgeon E. B.; Rodrigues, 3rd Class Assistant Surgeon J. M.; Browne, 4th Class Sub-Assistant Surgeon W. A.

MEDICAL SERVICES.

Members of the American, Chicago, and Harvard Units, Attached to Nos. 22 and 23 General Hospitals, Etampes: Dr. P. S. Chancellor, Dr. W. J. Dodd, Dr. W. E. Faulkner, Dr. V. Kazanjian, Dr. J. M. Neff.

The list also contains the names of a large number of non-commissioned officers and men, and also members of the nursing services.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

H.M.S. *Natal*.

THE year 1915 closed, as it had opened, with a naval disaster. On January 1st, 1915, the battleship *Formidable* was sunk in the Channel with the loss of the greater part of her complement. On December 31st the Admiralty announced that H.M.S. *Natal*, armoured cruiser, Captain Eric Back, R.N., had sunk in harbour on the previous afternoon as the result of an internal explosion. This is the third vessel which has been lost by an explosion in harbour since the war began, H.M.S. *Bulwark* and H.M.S. *Princess Irene* both having been destroyed in this way in Sheerness harbour. Out of a total ship's complement of 704 on the *Natal*, 14 officers and 373 men were reported as saved, while 25 officers, including the captain, and 292 men were killed. She carried three medical officers, of whom one, Fleet Surgeon E. S. Tuck, was saved, and two, Staff Surgeon A. Hooper and Surgeon (temporary) D. W. K. Moody, were lost. The locality of the accident has not been made known.

Staff Surgeon Alfred Oswald Hooper was educated at Edinburgh, where he graduated M.B. and Ch.B. in 1903, entered the navy in the following year, and became Staff Surgeon on November 21st, 1912.

Surgeon Douglas Whinster Keiller Moody was educated at Aberdeen, where he graduated M.B. and Ch.B. in 1900

and M.D. in 1902. He subsequently studied in London, Dublin, and Berlin, and filled the posts of house-surgeon of Peterborough Infirmary, assistant medical officer of the Central London Infirmary, and second house-surgeon of Addenbrooke's Hospital, Cambridge. He took a temporary commission as surgeon in the navy on August 10th, 1915.

ARMY.

Killed in Action.

Captain Anthony Purdon Hegarty Corley, M.D., killed in the Dardanelles last August, was the son of the late Anthony Corley, surgeon to the Richmond Hospital, Dublin, and president of the Royal College of Surgeons, Ireland. He was educated at Trinity College, Dublin, where he took the M.B., B.Ch., B.A.O., and M.D. in 1902. After qualifying he entered the Colonial Medical Service as a Government medical officer in Fiji. He subsequently settled in West Australia, where he served as Government medical officer successively at Wagin and Karridale and as medical officer of health at Pingelly. He joined the first Australian contingent as a combatant officer—captain in the 11th Infantry Battalion—on August 28th, 1914.

Major Frederick Miller Johnson, of the Australian Army Medical Corps, was killed at "Anzac" in the Gallipoli Peninsula, on November 29th. He was educated at Melbourne, and at Edinburgh, where he took the M.B. and C.M. in 1886 and the M.D. in 1888, subsequently studying also in Vienna and at Heidelberg. He then returned to Australia and went into practice at Melbourne, receiving the degree of M.D. *ad eundem* from the university of that city. He was attached to the 6th Australian Field Ambulance when killed. He was a grandnephew of the late Sir William Gull.

Captain Guy Fitzmaurice John Luther, of the Australian Army Medical Corps, killed in the Dardanelles last August, was educated at Trinity College, Dublin, and took the diplomas of L.R.C.S.Ire. and L.R.C.P.Ire. in 1893. After serving as house-surgeon of the City Hospital, Dublin, he went to Australia, where he filled the post of assistant physician to the Goodna Asylum, Queensland, and then settled in practice at Bundaberg, Queensland.

Captain Albert Guy Miller, R.A.M.C., was killed in France on December 29th, aged 31. He was the fourth son of the late Albert Miller, of Whernside, Toorak, Melbourne. He took a temporary commission as Lieutenant on October 21st, 1914, and was promoted to Captain on completion of a year's service. He was attached to the 12th Battalion Middlesex Regiment.

Lieutenant Arnold Bosanquet Thompson, R.A.M.C.(T.F.), was killed in the Mediterranean (Dardanelles?) on December 25th, aged 29. He was the fourth son of Arthur Thompson, Esq., of Garthlands, Reigate Heath, and of 38, Mincing Lane, London, and was educated at Oxford, where he took the M.B. and Ch.B. in 1914, and at the London Hospital. He was serving in the 1/3rd East Lancashire Field Ambulance.

Lieutenant William Frank Thompson, R.A.M.C., was killed in France on January 1st, aged 28. He was the elder son of W. W. Thompson, Esq., of 3, The Avenue, Brondesbury, was educated at the Leys School, Cambridge, and at Bath, and took the M.R.C.S. and L.R.C.P.Lond. in 1912.

Died of Wounds.

Lieutenant Manockji Burjorji Patel, I.M.S., whose name was in the casualty list as wounded in the battle of Ctesiphon, in Mesopotamia, on November 22nd-24th, has since been reported as having died of his wounds. He took the Scottish triple qualification in 1908, and also the D.P.H., Wales, in 1910. After serving as medical officer of the Madras and Southern Mysore Railway, he went into practice at Khambala Hill, Bombay. He took a temporary commission in the I.M.S. from June 9th, 1915. He is the third Indian-born member of the I.M.S. to fall in the present war, but the first Parsi, and also the first of the temporarily commissioned officers.

Died on Service.

The death is reported, while serving with the Expeditionary Force in France, of Miss M. E. Wilson, Queen Alexandra's Imperial Military Nursing Service, Reserve of Queensland, Australia.

Wounded.

Captain J. E. Brydon, R.A.M.C.(T.F.), Flanders.
Lieutenant R. C. Macmillan, R.A.M.C. (temporary), Flanders.

In the list of medical men killed serving as combatants, published in the BRITISH MEDICAL JOURNAL of December 25th, 1915, was given the name of Captain B. M. Hughes, M.R.C.S., of the 1/4th Norfolk Regiment. We are informed that Captain Hughes had been promoted to Major shortly before his death.

MEDICAL STUDENTS.

Beasley, James Joyce, third year medical student, Trinity College, Dublin, Second Lieutenant 6th Battalion Royal Irish Fusiliers, missing, believed killed, in the Dardanelles. He got his commission on September 28th, 1914.

Black, Thomas Samuel Cuthbert, fifth year medical student, Trinity College, Dublin, Private 7th Battalion Royal Dublin Fusiliers, died at Alexandria of wounds received in the Dardanelles.

Elliott, Thomas Cecil Moore, third year medical student, Trinity College, Dublin, Private 7th Battalion Royal Dublin Fusiliers, killed in action at the Dardanelles.

Gamble, Richard Maurice Brooks, third year medical student, Trinity College, Dublin, Second Lieutenant 7th Battalion King's Liverpool Regiment, killed at Festubert, in France, on May 17th, 1915. His commission was dated September 5th, 1914.

Heuston, Frederick Gibson, fourth year medical student, Trinity College, Dublin, Second Lieutenant 6th Battalion Royal Irish Rifles, killed in the Dardanelles. He joined on September 22nd, 1914.

Levis, George John France, second year medical student, Trinity College, Dublin, Private 5th Battalion Royal Inniskilling Fusiliers, killed in action in France.

Levis, James Henry Bruce, second year medical student, Trinity College, Dublin, Second Lieutenant 6th Battalion Royal Irish Rifles, killed in the Dardanelles. His commission was dated November 6th, 1914.

Murphy, James Neville Herbert, third year medical student, Trinity College, Dublin, Second Lieutenant 5th Battalion Royal Dublin Fusiliers, killed in Flanders, on May 10th, 1915. He got his commission on August 15th, 1914.

Nelis, James Edward Thornhill, third year medical student, Trinity College, Dublin, Lieutenant 5th Battalion Royal Inniskilling Fusiliers, killed in the Dardanelles. He was commissioned from November 19th, 1914.

Snell, Philip Sidney, third year medical student, Trinity College, Dublin, Second Lieutenant 6th Battalion Royal Irish Fusiliers, killed in the Dardanelles. His commission was dated September 28th, 1914.

Toomey, Archibald Roche, fifth year medical student, Trinity College, Dublin, Second Lieutenant 6th Battalion Leinster Regiment, killed in the Dardanelles. He joined on November 28th, 1914.

DEATHS AMONG SONS OF MEDICAL MEN.

Hudson, Arthur Frederick, Corporal 16th Battalion Canadian Scottish, eldest son of Dr. Hudson, of British Columbia, late of Cobham, Surrey, killed at Ypres on April 22nd, aged 21.

Lee, Charles Stewart, Second Lieutenant Royal Engineers, only child of Lieutenant-Colonel W. A. Lee, I.M.S.(ret.), killed in France on December 30th, aged 19.

Wight, Ronald Toynbee, Loyal Sussex Hussars, only son of T. H. Toynbee Wight, M.D., Harvard, died on October 30th in hospital at Malta, of dysentery contracted in the Dardanelles, aged 20.

TRINITY COLLEGE, DUBLIN.

We are indebted to Professor Dixon, of Trinity College, Dublin, for a roll of honour of the medical school of that university up to a recent date. Eleven graduates and fifteen undergraduates have been killed in action, while thirteen undergraduates at least are known to have been wounded.

The eleven graduates are Staff Surgeon W. G. Moore-Anderson and Surgeon G. Taylor, R.N.; Major E. B. Steel, Captain C. T. Conyngham, temporary Captain J. N. Armstrong, Lieutenant W. O. W. Ball, and temporary Lieutenants G. M. M. Fleming and J. A. Macmahon, R.A.M.C.; Captain G. F. J. Luther, Australian A.M.C.; Captain A. P. H. Corley, Australian Infantry; and Dr. P. N. Gerrard of Singapore. Brief notices of Captains Luther and Corley are given above. The others have all received a tribute in the JOURNAL already.

Notices of four of the undergraduates—Captain R. P. Tobin, and Lieutenants G. F. Dobbin, J. R. Duggan, and H. H. Warnock—have already appeared in the JOURNAL. Brief notices of the others are given above.

The thirteen undergraduates wounded are Captain W. C. L. Shee, Lieutenants G. C. Ballentine, F. F. J. Battersby, A. L. Gregg, E. J. Hamilton, G. W. Holmes,

C. F. Kennedy, C. R. E. Littledale, J. McClelland, A. A. Murphy, G. R. G. Smyth, and R. L. Vance, and Private G. G. Allardyce. Lieutenant Holmes is an Irish international football player. Lieutenant Vance has just passed his final examination, having qualified while on leave.

NOTES.

MEDICAL OFFICERS WANTED. *The Welsh General Hospital.*

THIS hospital, to which we have already referred, is a general hospital of 1,040 beds, the personnel of which is being raised by Wales for overseas service. The medical staff includes officers in charge of medical and surgical divisions, an ophthalmologist, pathologist, radiographer, and ear and throat specialist. A dental surgeon with a medical qualification will also be accepted. Appointments are for temporary commissions for service with the hospital. Officers who already hold temporary commissions or Territorial commissions are not accepted, with this exception, that the officers in charge of the medical and surgical divisions, who should be consultants in their own branches, may be transferred from Territorial units if they can be spared. The hospital is under the command of Lieutenant-Colonel A. W. Sheen, R.A.M.C.(T.F.), and leaves probably some time in February next. Forms of application for posts can be obtained from the Hon. Secretaries, Welsh Hospitals Offices, 47, Principality Buildings, Cardiff.

2/2nd South Midland Mounted Brigade Field Ambulance.

Medical officers are urgently wanted for this unit, at present stationed at King's Lynn. They must be prepared to sign for foreign service. Applications to Major A. G. Magrath, Officer Commanding 2/2nd South Midland Brigade Field Ambulance, London Road, King's Lynn.

2/3rd South Midland Mounted Brigade Field Ambulance.

A medical officer is required for this unit, which is stationed at Oxford for the winter. Full particulars can be obtained on application to the Officer Commanding, 1, Ifley Road, Oxford.

EMOLUMENTS OF MEDICAL OFFICERS TERRITORIAL OR WITH TEMPORARY COMMISSIONS.

Major R. Eager, O.C. 2/1st Wessex Field Ambulance, writes: In your issue of December 25th, 1915, I note that an officer commanding a Territorial Field Ambulance is asking for five medical officers, and as an inducement states, "rates of pay, etc., higher than temporary commissions abroad." I should be obliged if this commanding officer will explain to me and the rest of your readers how he can substantiate this statement. We have communicated with the O.C. in question, and in reply he refers Major Eager to the JOURNAL of October 30th, p. 662.

Scotland.

WESTERN INFIRMARY, GLASGOW.

At the Christmas meeting at the Western Infirmary, Glasgow, it was announced that the building scheme had been completed, and the new departments were formally opened. The meeting was held in the new admission department. The chairman of the Board of Managers, Sir Matthew Arthur, Bt., who presided, said that the new block in addition to providing a new admission department connected the new wing with the main building, and supplied the operating theatres and administrative rooms required. The admission department was the groundwork of the scheme, and it had been possible to carry it out owing to the gift of £16,000 by the Davis trustees. Rooms were provided in which minor operations could be performed on slighter cases and casualties and the patients cared for until they were able to leave. Such cases often came in at night, and if taken to the wards the patients there were disturbed. On the floor above had been built what was recognized by experts as one of the most perfect operating theatres in existence. Its cost, £3,500, had been defrayed by Mr. William Robertson, who had also defrayed the cost, £8,000, of the large ward in the new wing. While the new building would help the efficiency of the infirmary, it would not increase the annual expenditure, and did not add to the number of beds. The year had been a strenuous one; some of the physicians and surgeons were entirely engaged in war work, while the remainder combined it with their other duties. The medical superintendent, Colonel Mackintosh, M.V.O., and the matron, had been incessant in their labours. The infirmary had provided 100 beds for wounded soldiers, and it was fortunate that the dispensary was so planned that the hall made an excellent ward of 50 beds, from which the patients could

be easily taken to the consulting rooms and operating theatres. By affording facilities for the training of nurses the infirmary rendered a great service to the community; the value of trained nurses had never been more fully realized. The Davis Admission Department, and the William Robertson Operating Theatre, were then declared open by Miss Davis and Mr. Robertson respectively. Colonel Roxburgh, the convener of the House Committee, in moving a vote of thanks to the donors, said that the hospital was now practically complete in every respect, and unless some special gift were given for some special purpose he did not think that any further expenditure on building need be anticipated.

GLASGOW ROYAL INFIRMARY.

In addressing the nurses at the Glasgow Royal Infirmary on New Year's Day, the Lord Provost said that practically all the members of the medical and surgical staff were doing military duty; thirty-eight held commissions in the Royal Army Medical Corps, and twelve were engaged in Red Cross hospitals. Of those who held commissions, twenty-five were so actively employed on war duty that they were not available for the ordinary work of the infirmary; nevertheless it had gone on as usual. Eight wards, with an aggregate of 150 beds, had been set aside for the treatment of wounded sailors and soldiers, but this had not been allowed to encroach upon the accommodation for civilian cases. The chairman of the board of managers said that the number of civilian cases admitted was 9,982, a slight increase on the previous year. The number of sailors and soldiers admitted was 713. The daily average number of in-patients was 663.

ROYAL INFIRMARY, EDINBURGH.

From the annual reports of the Board of Managers it appears that the number of patients treated in the Royal Infirmary, Edinburgh, in the year ending September 30th, was 13,102, an increase of 284 on the previous year, which was the largest previously on record. The average daily number of patients was 903, compared with 847 in the previous year. In spite of this the deficit of ordinary income over ordinary expenditure showed a diminution of £9,687; at the same time the voluntary contributions had gone up by nearly £11,000, an increase of more than 50 per cent. The Board had set apart 200 beds for naval and military patients, and was prepared to give more if required; at the end of the year the number of such patients in the infirmary was about 160. To meet this special demand the managers had opened two spare wards and introduced extra beds temporarily in other wards; in addition a number of Territorial soldiers had been admitted to the general wards, and many of them had been submitted to operation to fit them for service. At the beginning of the war the managers had suspended the practice of charging for service patients in view of the great national emergency, but having learnt that other large hospitals had reconsidered their position in this respect, notice was given to the Admiralty and to the War Office that payment at the rate of 4s. a head a day would be accepted for all men treated after October 1st, 1915. The Army Council, however, had refused to make any donation in respect of the men who had been treated previously. Since the commencement of the war 61 nurses had been supplied directly to the War Office by the infirmary, and in addition a large number of former nurses were now serving in military hospitals. The complete roll contained 252 names, and of these 170 were on service abroad and 82 at home. The number of applications for nursing training had increased during the year from 695 to 1,051.

Ireland.

MAJOR EDWIN STEEL.

A LECTERN placed in the chapel of the Dr. Steevens's Hospital, Dublin, by the governors and staff to the memory of Major Edwin Bedford Steel, R.A.M.C., has been dedicated by the Archbishop of Dublin. Steel was for several years a resident pupil in the hospital, where the thoroughness of his work and the sterling qualities of his character made him many warm friends. He graduated in medicine in the University of Dublin in the summer of

1893, and in January, 1895, entered the Royal Army Medical Corps. He was for two periods in India, where he specially distinguished himself for his work in connexion with plague. He held the South African War Medal and the Durbar Medal. In August, 1914, he went to France in command of Field Ambulance No. 20, and for his work with it was mentioned in dispatches by Sir John French. In October, 1914, Steel was appointed Assistant Director of Medical Services with the First Cavalry Division. While on this duty he was, on November 23rd, wounded at La Clytte by shell fire, and died the same day. The handsome brass lectern in the chapel of his old hospital will form a visible token of the honour in which the memory of Edwin Steel's short but full life is held by some of those who knew and loved him well.

SMALL-POX IN COUNTY FERMANAGH.

Dr. McCormack, Local Government Board Medical Inspector, who attended a meeting of the Lisnaskea board of guardians, said that he had been directed to confer with the medical officer, Dr. Knox, in regard to the two reported cases of small-pox in the Fever Hospital. Isolation was absolutely necessary, and, in addition, systematic observation of all the contacts, along with the destruction, by fire, of the bedding and clothing that came in contact with the patients, the thorough disinfection of the infected premises, and the vaccination of all contacts. Those measures, so far as possible, had already been carried out by Dr. Knox. The nurses in the fever hospital had been vaccinated, and the small-pox cases were being treated in the upper, and the other cases of infectious disease in the lower, wards of the hospital. Communication between the nurse attending the small-pox cases and the nurse attending the other patients had been forbidden as far as possible. Should other cases of small-pox arise the board of guardians would have to consider the advisability of erecting a self-contained pavilion. The Lisnaskea Union was a "partially vaccinated community." In the Derrylin dispensary district there were 111 defaulters in the last quarter, which number was about equal to the annual birth-rate. The board should make arrangements to have primary vaccination carried out as quickly as possible.

England and Wales.

THE SANDLEBRIDGE COLONY FOR THE FEEBLE-MINDED.

The report presented to the annual meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded stated that the Mental Deficiency Act, 1913, had proved of great value in stimulating the work of the Sandebridge Colony. A considerable number of committees formed under the Act had applied to the society for places, but it had been necessary to refuse the applications, as the provision for permanent care so far made at Sandebridge had been only designed for inmates who had been received as children and suitably taught and trained. A subcommittee had, however, been formed to consider the possibility of building an additional house for lower grade children. The operations of the Elementary Education Act, 1914, had brought increased calls on the accommodation from educational authorities, and the vacancies at the disposal of the management were altogether inadequate. There had been a constant growth in numbers since the year 1902, when there were only 20 boys and girls in the institution, until at present there were about 300 inmates. Miss Dendy, the pioneer of the institution, gave an interesting account of the work done by the inmates. The girls had made 800 pairs of socks for soldiers since the war began and the boys had soled and heeled over 900 pairs of boots and shoes. The financial account showed a total income of £11,647, which included £7,630 from local authorities, and there was a credit balance of about £2,000. On the farm account there was a profit of over £620.

ATTENDANCE ON PANEL PATIENTS DURING THE WAR IN MANCHESTER AND SALFORD.

At a meeting of the Manchester Insurance Committee held on December 28th, the chairman, Mr. Walter Davies, in drawing attention to the minutes of the Medical Benefit Subcommittee, specially referred to the new commercial

tariff, which provided that chemists should be paid in full. The arrangements had been completed, and Manchester and Salford would now work out a scheme for the two areas conjointly, while other parts of the country would be mapped out into areas. He hoped and believed that the chemists would now be satisfied, as they would receive their 100 per cent.

Mr. Davies also drew attention to the treatment of insured persons during the war. A large demand was now being made on the medical men of Manchester to join the forces, and the committee had had to consider two circulars, one from the Medical War Committee and the other from the Insurance Commissioners, setting forth what they felt was their duty towards the civil population. The committee had been in communication with the local War Committee and the Panel Committee, and they had agreed jointly to a scheme which would secure to every insured person adequate medical attention. Many of the Manchester doctors had entertained conscientious objections to the insurance scheme, and had refused to go on the panel, but they had now been appealed to on the grounds of patriotism, and it had been made clear to them that if some of the profession had to go to the war it would be necessary for non-panel doctors to render aid to insured persons. A scheme had now been arrived at whereby the whole of the panel doctors and also those not on the panel had agreed to attend any insured person who cared to go to them. The patriotism the doctors had shown in this matter deserved acknowledgement. Several members of the committee also congratulated the doctors on their patriotic action, and Mr. Davies further expressed the hope that while every effort was being made to obtain an adequate service, insured persons would not put any undue strain on the resources of the committee, but would only seek the services of a doctor when it was really necessary.

It appears that the position in Manchester is not quite so straightforward as described by Mr. Davies, as in a letter which appeared in the *Manchester Guardian* on December 31st, 1915, signed by Dr. E. W. Floyd, it is stated that it is incorrect to say that the non-panel doctors had agreed to treat panel patients. At a meeting of non-panel practitioners, held on December 29th, to consider the War Committee's proposals, the two following resolutions were passed with only three dissentients, who were members of the War Committee:

1. That this meeting of non-panel practitioners heartily supports the general lines of the scheme for the conservation of the private practice of practitioners on service.
2. That they cannot accept as it stands the scheme for attendance on insurance patients, but will require it to be expressly stated that home panel practitioners shall be responsible for attendance on all panel patients.

A copy of these resolutions to be sent to all the papers which published Mr. Davies's statement.

Canada.

CANADIAN GRADUATES AND THE R.A.M.C.

The regulation by which a graduate of a Canadian medical school was required to obtain a provincial licence to practise before he could join the R.A.M.C., to which Sir Donald MacAlister made reference in his presidential address to the General Medical Council, has since been altered, and it is now possible for a graduate of any Canadian medical school of recognized standing to join the R.A.M.C. or the C.A.M.C. without first obtaining a licence to practise in the province in which he has graduated. The obligation has resulted in unfortunate delays and disappointments in the past, and its removal will facilitate the completion of arrangements between the Dominion of Canada and the Mother Country.

ALBERTA MEDICAL ASSOCIATION.

At the tenth annual meeting of the Alberta Medical Association, which was held at Banff, under the presidency of His Honour Lieutenant-Governor R. G. Brett, M.D., reference was made to the offer of a fully-equipped hospital of 1,040 beds for service overseas, made to the military authorities by the University of Alberta. The offer had been refused for the time being, but the

association wished to express its willingness to assist in the matter and accordingly the following resolution was passed:

That the Alberta Medical Association puts itself on record as being strongly in favour of a scheme to form a hospital unit to be placed at the disposal of the War Office and to be called upon when required; and also that the Association is in favour of authorizing the Alberta College of Physicians and Surgeons to support, as fully as its finances will permit, the organization of the hospital unit.

The association also resolved to support the efforts of the Alberta Nurses' Association to obtain registration.

The subject of the presidential address was the "Social Evil." Dr. Brett quoted statistics to show the terrible effects of the two diseases considered under this heading, and strongly impressed upon the profession the necessity for further enlightenment of the public in the matter of prevention and cure. Other interesting papers were read, among them one by Dr. Whitelaw, medical officer of health at Edmonton, on the Public Health Act. The next annual meeting of the association will take place at Edmonton, under the presidency of Dr. Whitelaw.

SERUMS SUPPLIED FREE.

The Ontario Board of Health has announced its intention of supplying free, from February 1st, 1916, to physicians, hospitals, health boards, and the public generally throughout the province antitoxins and serums for diphtheria, small-pox, meningitis, tetanus, rabies, and other diseases. The appropriate material, which will be prepared in the laboratories of the University of Toronto, will be supplied free to any applicant, on presentation of a physician's prescription, by institutions formed by the department. It is estimated that for diphtheria alone from 150,000 to 200,000 doses may be needed within the year, and provision will be made for at least 500,000 doses of typhoid vaccine. During the present war the Ontario Board of Health has supplied large quantities of anti-typhoid vaccine for use amongst the troops. Down to May, 1914, the cost of serums annually imported into Canada was 120,000 dols. At that time, however, an arrangement was made with the University of Toronto whereby antitoxin could be supplied to boards of health and druggists at a much reduced rate. The splendid results obtained at the Isolation Hospital, Toronto, through the use of antitoxin in diphtheria, where the death-rate has been reduced from 16 to 6 per cent., has largely influenced the Board of Health in deciding to prepare the vaccine and supply it free of charge.

Correspondence.

OUR BELGIAN COLLEAGUES.

SIR,—The wind up of the year brings back to my mind the events which occurred a year ago at the same period, when you gave me the opportunity to expose to you the sufferings of my country-folk, the crimes committed in Belgium, the sad situation in which so many Belgian doctors and pharmacists were living.

Under the management of a medical committee, you immediately called upon the spirit of fellowship of the members of our corporation, and I enjoyed the moving consolation to find that your call was responded to from all quarters of the world.

On behalf of my colleagues in Belgium, and although I have been unable for a good while to communicate with them, I grasp this opportunity to deeply express to you, to the chairman and gentlemen of the committee, my heartfelt thanks for the lasting effort made by all of you during the past year. The voices of all those you have so generously assisted in their sufferings, of whom you may have saved life, cannot yet reach you; the Germans are still there to prevent it. Later on, when we shall be freed, when we will be able to think again and to express freely our feelings, they will tell you themselves—better than I could—the greatness of your assistance.

I will only now beg you to accept the gratitude of the Belgian doctors and pharmacists—the gratefulness of their little children, which must bless you at the distance.—I am, etc.,

London, W., Dec. 31st, 1915.

C. JACOBS.

THE TONSILS.

SIR.—Arising out of your review of a monograph on *The Tonsils* by Dr. Barnes (U.S.A.), two letters have recently appeared in the JOURNAL, one from Dr. Mechan on December 25th, 1915, p. 948, and another from Dr. Syme on January 1st, 1916, p. 33, which appear to me to call for comment.

Dr. Syme lays it down without qualification that "when surgical interference is necessary" the "only operation applicable" is "enucleation of the tonsil"; that is to say, total removal of the whole tonsil *en masse* complete in its capsule. Whilst agreeing that total removal should be the operation of choice in the general run of cases, more especially in children, yet most of us would hesitate, and so probably would Dr. Syme, to eviscerate the entire tonsillar bed in trained singers and other adult professional voice users, on account of the danger of altering the form and deranging the muscular mechanism of the fauces from post-operative adhesions.

Dr. Syme makes no dogmatic statement as to the technique to be employed in effecting enucleation, holding doubtless that there is considerable room for eclecticism on that question.

Not so Dr. Mechan, however, who, while lauding complete removal by the old combined dissection and finger technique favoured by general surgeons thirty years ago, proceeds utterly to condemn the employment of the guillotine for the removal of tonsils. Dr. Mechan appears to be under the misapprehension (in common, doubtless, with many others) that the technique of the modern guillotine operation resembles that carried out in the last century, when many operators were satisfied with a subtotal removal. It was, however, shown in 1910 by Whillis of Newcastle and by Sluder of Chicago that in most instances the tonsils could be completely and rapidly enucleated by means of a modification of the Mackenzie guillotine method, provided the shaft was rigid and the edge of the blade was dull rather than sharp. The methods of technique employed by Whillis and by Sluder respectively, though differing in detail, are similar in principle, but it is unnecessary to my point to enter into particulars.

The outstanding facts are that most specialists now aim at the complete removal of a diseased tonsil *en masse* in the general run of cases, more especially in children, and that such enucleation can be carried out by experts, (1) in every case by one or other of the various modern dissection methods, (2) in nearly every case by the modern guillotine method alone, and (3) in a somewhat less number of instances by the snare and vulsellum only.

Many specialists, more especially those who favour the snare method, resort to a preliminary dissection in difficult cases and finish up either with the snare or with the blunt guillotine. Others prefer and employ some form of dissection method throughout as a routine measure, without resorting to the snare or guillotine, either alone or as an adjunct. Such an attitude of personal preference for dissection methods, however, does not imply any agreement with Dr. Mechan's allegations as to the inutility of the Mackenzie type of guillotine in radical removal of diseased tonsils, whether enlarged or otherwise. In many clinics in this country, where school children are operated on, and where nothing less than total removal of the tonsils is invariably aimed at, the enucleating guillotine method of Whillis alone is consistently and successfully employed for that purpose.

It may be mentioned that to such a pitch of perfection has enucleation with the guillotine been brought that La Force in America and Elphick in this country have actually gone so far as to devise haemostatic guillotines in order to deal with enlarged tonsils in haemophilics and in anaemic children.

The whole subject was recently reviewed in a paper by the last-named and myself, read at the annual meeting at Aberdeen in 1914, and published in full in the *Journal of Laryngology*, December, 1914.¹—I am, etc.,

London, W., Jan. 4th.

WILLIAM HILL.

THE AUSCULTATION OF THE HEART.

SIR.—I think it is time we recalled the motto, "Honour where honour is due." Is it not the fact that the late

¹ A short abstract was published in the *BRITISH MEDICAL JOURNAL*, 1914, vol. ii, p. 1019.

Dr. George Gibson of Edinburgh was the first to point out that murmurs are not evidence of heart disease? I have heard him relate that many times he had secured admission of young candidates for commissions in the army by means of delay and a period of rest. I think it is also the fact that Sir James Mackenzie pointed out in his address in memoriam of this great physician that it was he who had shown the way in all the new discoveries in regard to heart pathology and diagnosis.—I am, etc.,

W. HALL CALVERT Capt. R.A.M.C.(T.).

Crieff, Dec. 29th, 1915.

THE DEMAND FOR LOCUMTENENTS.

SIR,—May I through your columns appeal to practitioners requiring locumtenents during their absence at the front or otherwise not to be misled by misrepresentations that, owing to the scarcity of men, they will have to pay 9 or 10 guineas a week to secure deputies? As a matter of fact, owing to the generous way in which retired and elderly practitioners have come forward to assist, besides those returning from the front and those ineligible for military service, the supply of locumtenents is at present in excess of the demand, and trustworthy men can be had at 7 guineas a week in most cases, or less if with their wives, and in the interests of recruiting I trust all requiring help will refuse to pay the excessive fees in some cases demanded, especially by men who should be doing their duty in the R.A.M.C.—I am, etc.,

London, W.C., Jan. 3rd.

PERCIVAL TURNER.

STATE REGISTRATION OF NURSES AND THE RED CROSS SCHEME.

SIR,—The circular from the Red Cross Society on the proposed nursing college* is an immensely important matter, and the hospitals of the country should be very wide awake. After the war the nursing profession runs the risk of being flooded by partially-trained nurses.

The nurses should claim to be put under similar government to the Central Midwives Board. The hospitals of the country must take prompt action to nip this Red Cross scheme in the bud. Let them force Government action, so as to have State regulation and guarantee of the training, examination, and registration of nurses. There is grave risk of the status of the nursing profession being seriously lowered.—I am, etc.,

Wigan, Jan. 4th.

FERDINAND REES.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on December 15th, 1915.

Treasury War Grants.

It was reported that the Lords Commissioners of the Treasury had, on the recommendation of the Advisory Committee on University Grants, made, under certain conditions, a special grant to the University of £3,500 in respect of the years 1914-15 and 1915-16 together to cover loss of income caused by the war, and that grants of £10,500 and £7,000 respectively had been made by the Treasury to University College and King's College for the same purpose. It was resolved to transmit to the Treasury the thanks of the Senate for the grants.

Brown Animal Sanatory Institution.

Dr. Edward Mellanby, M.D., was appointed Acting Superintendent of the Brown Animal Sanatory Institution during the absence of the Superintendent, Mr. F. W. Twort, who had received leave of absence in order to organize, for the War Office, base laboratories in the Eastern theatre of war.

Professor of Protozoology.

Dr. H. M. Woodcock, assistant to the Professor of Protozoology, was appointed acting head of the Department of Protozoology at the Lister Institute of Preventive Medicine, and was subsequently granted leave of absence to undertake special service at one of the Mediterranean base hospitals.

Personnel of the Senate.

It was reported that Professor F. W. Andrewes, M.D., F.R.C.P., F.R.S. (St. Bartholomew's Hospital Medical School), and Sir Cooper Perry, M.D., F.R.C.P. (Guy's Hospital Medical School), had been appointed the representatives of the faculty of medicine on the Senate, in the place of Mr. H. L. Eason, M.D., M.S., and Sir Wilmot Herringham, C.B., M.D., F.R.C.P., resigned.

* See page 60.

Chairmen of Committees.

Sir Rickman Godlee, Bt., K.C.V.O., and Sir Seymour Sharkey, M.D., F.R.C.P., have been elected chairmen of the Brown Animal Sanatory Institution Committee and the Graham Legacy Committee respectively.

University Medal.

The university medal at the M.B. B.S. examination for internal and external students, October, 1915, has been awarded Geoffrey Challon Linder of St. Bartholomew's Hospital.

Gilchrist Studentship for Women.

Applications for this studentship must reach the Academic Registrar not later than the last day of February. The studentship is of the value of £100, tenable for one year by a graduate of the university who is prepared to take a course of study in an approved institution for some profession. Candidates must have graduated in honours in the University of London, and must be of not more than three years' standing from their first graduation.

UNIVERSITY OF SHEFFIELD.

THE following have passed the examinations indicated:

THIRD M.B., CH.B.—G. E. Hill, Elizabeth E. Jenkins, B. H. Rae.
D.P.H.—Beatrice Garvie.

UNIVERSITY OF EDINBURGH.

THE annual report for 1915 states that the total number of matriculated students was 1,853, being 676 fewer than for 1914, and 1,408 fewer than for 1913. There were 807 students, including 11 women, in the Faculty of Medicine, a decrease of 218. Of the students of medicine, 382, or over 47 per cent., belonged to Scotland; 122, or over 15 per cent., were from England and Wales; 30 from Ireland; 80 from India; 193, or nearly 24 per cent., from the British Overseas Dominions and Dependencies; and 26 from foreign countries.

The University roll of war service—embracing members of the staff, graduates, and students, past and present—which a year ago contained about 1,700 names, has now reached a total of nearly 4,000, to which should be added about 400 who are members of the Officers' Training Corps. The University authorities have renewed, with modifications, various concessions made last year to students on service; and a number of scholarships, etc., which would, in ordinary course, have been tenable or open for competition this session, have been in the meantime suspended.

During the year the bequests of the James Cropper and the Waldie Griffith Scholarship Funds for the medical education of women in Edinburgh, were handed over to be administered by the university authorities, and the balance of the funds left over on the winding up of the Scottish Association for the Medical Education of Women has been given to the University Court for the foundation of an annual prize for a woman student qualifying in medicine.

The Services.

* EXCHANGE DESIRED.

ROYAL ARMY MEDICAL CORPS.

A LIEUTENANT R.A.M.C. (temporary), at present stationed in Lancashire, desires to exchange with an officer holding a temporary commission in or near London. In addition to his military duties the applicant is on the staff of the local military hospital. Applications should be addressed to No. 200, BRITISH MEDICAL JOURNAL Office, 429, Strand, London, W.C.

DR. HOWARD A. KELLY, of Baltimore, has given to the Johns Hopkins Hospital of that city more than 4,000 volumes, including books, monographs, and periodicals. The collection, which for the most part consists of literature dealing with obstetrics and gynaecology, is valued at £5,000. It is proposed to erect a suitable building for its reception.

THE bicentenary of the firm of Allen and Hanburys was celebrated last month, when the employees at home and abroad presented to the vice-chairman his portrait, painted by Mr. Percy Bigland, and to Mr. W. Ralph Dodd, a director, a silver centrepiece. The business was established in the City of London in 1715, and though the buildings have been rebuilt the site is the same. We gather that the business was founded by Mr. Silvanus Bevan in Plough Court, and that the first bearers of the name by which the company is now known were William Allen, F.R.S., President of the Pharmaceutical Society on its foundation in 1841, and Daniel Hanbury, F.R.S., whose name and work are commemorated in the Hanbury medal. Among the members of the firm at this time is Mr. Cornelius Hanbury, who joined it as a partner nearly sixty years ago; while Mr. F. J. Hanbury, the vice-chairman, has belonged to it for some forty years.

Obituary.

GEORGE OLIVER, M.D., F.R.C.P.,
FORMERLY OF HARROGATE.

It is with deep regret that we announce the death of Dr. George Oliver, which occurred at his residence, "Riversleigh," Farnham, Surrey, on December 27th, 1915.

He was born in April, 1841, and was the second son of Mr. W. Oliver, a surgeon of Middleton-on-Tees, Durham. He was educated at Gainford School, Yorkshire, and having decided to adopt his father's profession he proceeded to University College, London, and University College Hospital, where he had a brilliant academic career which culminated in his taking the Gold Medal at the M.D. examination of the University of London in 1873. Even in these early days he gave evidence of a truly scientific conception of his work, and he always had a deep admiration for William Sharpey, who was Professor of Physiology at University College in those days.

He started practice at Redcar, but he only stayed there a few years. In 1875 he went to Harrogate, where he speedily acquired a large practice, first as a general physician and subsequently as a consultant. He spent altogether thirty-three years at Harrogate, and was recognized as the highest authority there in the special branch of practice associated with that town. During the later portion of this period he used to reside at London or Sidmouth during the winter, only living at Harrogate for the season. In 1901, however, he purchased his beautiful Surrey home, where he spent the winter months, and it was not until 1908 that he entirely relinquished his Harrogate work.

This freedom from the claims of a busy practice during a long period of each year enabled him to prosecute original research, which he loved; some of this was carried out in the Physiological Laboratory, University College, London, but a good deal in his private laboratory in his own house. He was always clever at any mechanical device, and most ingenious and resourceful in overcoming difficulties. He wrote extensively not only on the Harrogate waters, but also on urine testing; the fourth edition of his *Bedside Urine Testing* was published in 1889, and his originality here was shown by the invention of the testing papers known as "Oliver's test-papers."

But it was always the blood and its circulation that most attracted his attention, and one instrument after another dealing with this branch of science was brought before the notice of the medical world; his haemacytometer, haemoglobinometer, arteriometer, and sphygmometer are instances. He will be especially remembered for his work in connexion with blood pressure; he it was among British physicians who chiefly insisted on the importance of estimating blood pressure in diagnosis, and the instruments of precision he introduced for this purpose will live long and keep his memory green. His book on *Blood Pressure* rapidly passed through two editions, and at the time of his death he was actively engaged in the preparation of a third, in which the book was practically rewritten. It is earnestly to be hoped that this work, which was nearing completion, may ultimately see the light.

Another branch of medical science to which he devoted himself was that relating to the ductless glands, and he published papers on the suprarenal, thyroid, thymus, and pituitary bodies. In this direction he is perhaps best known by the epoch-marking paper, published in conjunction with Professor Sir Edward Schäfer on the suprarenal glands. This really formed the foundation for all the enormous amount of subsequent work on the adrenal body which has resulted not only in the elucidation of the functions of this formerly mysterious organ but also in the discovery of the active principle, adrenalin, one of the greatest boons to suffering humanity. Although Addison many years ago had dimly conjectured the use of the suprarenal capsule, it was not until Oliver and Schäfer published their famous paper that any clear light was thrown upon the subject.

In 1887 Dr. Oliver was elected Fellow of the Royal College of Physicians of London, and a few years later, with characteristic generosity, he founded there, in memory of his old master Sharpey, the lectureship which now bears

the name of the Oliver-Sharpey Lectureship. Dr. Oliver was most suitably chosen as the first lecturer under this trust, when he took as his subject, "Studies on tissue-lymph" (1904). He had previously filled the position of Croonian lecturer at the same college (1896), which gave him the opportunity of bringing prominently before the profession the importance of a study of blood pressure.

This does not by any means exhaust the list of his writings, for he contributed largely to the journals, and also to standard works, such as *Quain's Dictionary of Medicine*, for which he wrote articles on constipation and on other ailments of the bowels. He was thus a man of wide attainments; his recreations included photography, in which he became an expert, and until the last few years he took his exercise mostly in the form of bicycling. He was never a man of strong physique, but, in spite of this, continued to live an active and strenuous life. About five years ago he had an attack of haematemesis, from which he fortunately quickly recovered; for about a month before he died he suffered from some bronchial catarrh, and the coughing so occasioned evidently strained the weak spot in his gastric lining. On Christmas night he was again seized with bleeding, which no remedy could check, and in two days he peacefully passed away.

His great aim throughout life was to make medicine a more exact science than he found it, and none can deny that he succeeded in this great endeavour; the keynote of his success, both at the bedside and in the laboratory, was untiring perseverance; he was never satisfied with anything that was imperfect, but went steadily on, altering and improving his inventions until they gave absolutely correct results. It was the same with his writings: he wrote and rewrote each sentence until it was absolutely clear, so as to express his meaning in the fewest possible words. He never hesitated to change his views when necessary, and much of what he wrote in his earlier editions was consequently amended as his apparatus was perfected and gave him results which corrected those obtained with less perfect instruments.

He was a man of a singularly sweet, genial, and unselfish disposition, which endeared him to his patients and his friends. He will be greatly missed not only in the scientific world, but also by the large circle of his personal friends in Yorkshire, London, and Surrey.

During the time he was at Redcar he married Alice, the only daughter of Mr. J. Hunt, of Barnard Castle, by whom he had one son and one daughter, who survive him; she died in 1898. In 1900 he married again Mary, daughter of Mr. W. Ledgard, of Roundhay, Leeds, and she also survives to mourn her irreparable loss. He was buried in the churchyard of the peaceful little church at Tilford on December 31st, the church which he used so faithfully to attend.

SIR GEORGE SCOTT ROBERTSON, K.C.S.I., M.P.

WE regret to have to record the death of Sir G. S. Robertson, so well known as the defender of Chitral in 1895. He was born in London in 1852, but both his parents belonged to Orkney families. He received his medical education at the Westminster Hospital Medical School, and took the diploma of L.S.A. in 1876, and that of M.R.C.S. in 1877. He entered the Indian Medical Service in 1878, and his first Indian experience was the Afghan war of 1879-80, when he served in the operations in and round Kabul in December, 1879, in the affair of Shekhabad, and in the operations in Kohistan, receiving the medal with a clasp. He then went into civil employment in the North-west, now the United Provinces, serving as civil surgeon successively of Bahraich, Meerut, and Ghazipur. In 1888 he entered the service of the Foreign Department as agency surgeon of Gilgit, a small dependency of Kashmir, on the extreme north-east frontier of the Indian empire. In 1890-91 he made a solitary expedition through Kafiristan, being the first European to explore that country, and gave an extremely interesting account of the year he spent amongst the wild hillmen in his first book, *The Kafirs of the Hindu Kush*. It was published in 1896, and in the interval he had an opportunity of showing his diplomatic powers in dealing with the hillmen when acting as chief political officer of the Hunza-Nagar expedition in 1891-92. For his services on this occasion he received the Frontier medal and was nominated C.S.I. In 1892 he installed the Mir of Hunza in the presence of the

Chinese envoys. Afterwards he was sent on a mission to Gor, was besieged in the Thalpen entrenchment, and present at the capture of Chilas. The following year he was sent on a political mission to Chitral at the extremity of the tribal country over which the Government of India exercises influence. In 1895 the ruler of Chitral was murdered by a rival, and the position of Robertson with his British and Sikh forces of 543 men, of whom 139 were non-combatants, became critical. The siege of Chitral began on March 4th, 1895, and it was not until April 20th that the relieving force arrived to find Robertson severely wounded. He was able, however, in September of the same year to instal the present ruler of Chitral. He was created K.C.S.I. in 1895, and appointed British agent in Gilgit. Afterwards he was political officer in charge of the late Ayub Khan. He was promoted surgeon-major in 1890 and lieutenant-colonel in 1898. He retired in 1899.

In the year after he came home Robertson contested Stirlingshire in the Liberal interest unsuccessfully. He was elected for Central Bradford in 1906. He did not achieve any prominent position in the House of Commons, but had recently shown by speech and question his anxiety to arouse the House and the Government to a sense of the peril in which the country stands.

In 1898 he published in a volume, entitled, *Chitral: the Story of a Minor Siege*, a very modest account of the events of 1895. He was an honorary D.C.L. of Trinity University, Toronto. He was twice married, and his second wife, the daughter of Mr. Samuel Laurence, the painter, survives him.

ALBERT WESTLAND, M.D.,
ABERDEEN (FORMERLY OF HAMPSHIRE).

WE regret to announce the death of Dr. Albert Westland, M.D., formerly of Belsize Park, Hampstead, and, for the last seventeen years, of Aberdeen, where he died on December 31st, 1915, at the age of 62. He had been ailing for the last year of his life, and was unable to attend to the numerous duties in which he was interested.

Dr. Westland was a son of the late Mr. James W. Westland, manager of the North of Scotland Bank, and was a brother of the late Sir James Westland, C.S.I., who had a distinguished career in the Indian Civil Service. In 1872 he obtained the degree of M.A., and in 1875 graduated M.B., C.M. with highest honours, being awarded the John Murray Medal and Scholarship as the most distinguished medical graduate of the year. In 1877 he proceeded to the degree of M.D.

After a visit of a few months to the Paris school of medicine and a short assistantship at Highgate, he became engaged in large and influential general practice in Hampstead, and here he practised from 1877 to 1898; during that time he gained the affection and respect of an ever-increasing *clientèle*, and his kindness, his skill, and his devotion to duty were recognized by his patients and friends in the presentation of a substantial testimonial when he left Hampstead to reside in his native city of Aberdeen. In Aberdeen he took a great interest in public affairs, local and imperial. He was an active and influential member of the Town Council for three years, and when, on account of his advocacy of a new scheme for water supply for which the inhabitants were not prepared, he was thrown out in an election in 1910, he did not seek re-election. He was often named as a probable Lord Provost of the City of Aberdeen, and had he consented to resume his connexion with the town council he would doubtless have been promoted to the civic head of the community. Dr. Westland had also been a member of the Aberdeen University Court as one of the representatives of the General Council since 1905.

His long residence in London made him thoroughly conversant with the conditions of English medical practice and with the views of graduates of the university resident in the metropolis and the south, and as a member from its foundation of the Aberdeen University Club in London, of which he was a vice-president, he had continuous opportunities of meeting and conferring with brother graduates of the university. Dr. Westland was strongly in favour of placing modern languages and literature on an equal footing with classics, and urged that in the medical

curriculum more time should be given to clinical study and that there should be a closer relationship between the medical school and the infirmary. During his tenure of office as a member of the court Dr. Westland took a considerable part in the organization of the quatercentenary celebrations, while he also assisted in bringing about important changes and reforms in the arts and medical curricula.

He was a ready and effective public speaker, and became president of the Aberdeen Liberal Association. He presided at the last meeting held in Aberdeen addressed by Mr. Lloyd George, but a few weeks after this meeting he publicly resigned the presidency as he resented the treatment meted out to the medical profession by the Insurance Act.

Dr. Westland was co-editor of the *University Review*, and when in London practice he wrote *The Wife and Mother* and *The Child*. Of these two works the former especially has been appreciated ever since it was published, and has gone through several editions. He was also editor of Thomson and Steele's *Dictionary of Domestic Medicine and Surgery*. Dr. Westland will be much missed. To his intimate friends he was known as a most engaging and delightful conversationalist. In university circles he will be particularly regretted, and he has left behind him the memory of a pleasant nature and a high record for diligence, ability, and integrity in the discharge of professional and public duty. He leaves a widow and two daughters.

ANDREW DUNLOP, M.D. EDIN., D.P.H., F.G.S.,
JERSEY.

By the death of Dr. Andrew Dunlop, which occurred at his residence at St. Helier, on December 30th, 1915, the profession in Jersey has lost its esteemed doyen. Recently Dr. Dunlop had been in failing health, and had suffered from heart trouble, but he had continued actively at work almost to the last, and the end (from cardiac failure) came rather suddenly. His death has called forth expressions of genuine regret and sorrow among all classes of the island community. Eloquent and emphatic testimony is borne in the local press to the affection and esteem with which he was regarded, special reference being made to his high personal character, his generosity, his native courtesy and gentleness, his genuine kindness and considerateness towards all seeking his advice, quite irrespective of class or station.

Dr. Dunlop received his medical education in Edinburgh, and graduated M.D. there in 1863. He settled in Jersey in 1868, and soon acquired an extensive general practice. His success was upon every ground well merited, and never left him. His fidelity towards his patients was absolute, and in the case of very many he was also the personal valued friend. So also towards his medical *confrères*, his loyalty and kindness were never in doubt. Dr. Dunlop held several honorary positions and appointments in connexion with the Jersey General Dispensary and other institutions, to which he devoted much time. He was one of the original founders of the Jersey Medical Society, was for a time its honorary secretary, and subsequently for some years its president. His medical contributions were numerous—an article on rupture of the heart written so far back as 1866 (*Edinburgh Medical Journal*) may be mentioned specially—all being marked by care and painstaking accuracy. In addition he was an enthusiastic geologist and contributed papers, all of interest and value, upon local geological features, as also on anthropology, to the leading scientific society in the island, the *Société Jersiaise*.

Recent years brought sad trouble in Dr. Dunlop's domestic circle—the death of a much-loved daughter, the loss of two sons in the South African war, and in the present conflict the falling of three other heroic sons, killed in action fighting for their country. The general sympathy—inclusive of royal condolence—has gone out towards the sorely stricken yet resolute parents in their heavy bereavement.

Dr. Dunlop was at one time Surgeon-Lieutenant-Colonel and Principal Medical Officer of the Royal Jersey Militia. He was 73 years of age. He leaves a widow, a married daughter, and two sons to mourn the loss of an attached and devoted husband and father.

It is with great regret we have to record the death, on December 17th, 1915, at the age of 55, of Dr. G. S. Morrison, Physician-Superintendent of Hereford County and City Asylum. He was the second son of Malcolm Brown and Rosalie Olivia Morrison, of Bhagalpur, and was born in India. He was educated at the University of Calcutta and the Royal College of Surgeons of Edinburgh. After taking the triple qualification in Scotland, he was for a time family physician to the late Earl of Elgin. Afterwards he was assistant medical officer to the Derby Asylum, and later was selected to fill a similar position at the County and City Asylum, Hereford, where he assisted his chief, Dr. T. A. Chapman. On Dr. Chapman's retirement a few years later, Dr. Morrison was appointed medical superintendent, which post he held until the day of his death. During his twenty years' service as medical superintendent he proved himself to be a skilful physician and a capable administrator, and was considered by the profession generally to be an authority in his speciality. As assistant medical officer he was one of the first to be selected to be put on the council of the Medico-Psychological Association, and afterwards was placed on the committee appointed to revise the constitution of that association with a view to assistant medical officers taking a more important part in its affairs and to revise the scientific work, which had gradually been allowed to take a secondary place in the affairs of the association. He took part in many debates when alterations were proposed which would give younger and junior members a more leading position than had been previously the case. He addressed himself to the assistant medical officers of that day, and by his vigorous action and forceful arguments he effected his purpose, and the existing constitution of the association, which has expanded its work and prosperity, was largely due to his unflagging efforts. He was Vice-President of the Section of Neurology and Psychological Medicine of the annual meeting of the British Medical Association when it met in Birmingham in 1911, and was recently President of the Worcestershire and Herefordshire Branch of the British Medical Association, and had for a considerable time acted as secretary, when he successfully worked to revive scientific work, which had been flagging for some years. Dr. Morrison was a man of many parts, courteous, sympathetic, and kindly. He enjoyed public respect and the affectionate regard of his afflicted patients, who learned to value him as their trusted and beloved friend. His love for the suffering poor was conspicuous, and his consideration at all times given them, irrespective of caste or creed.

DR. JOHN RIMINGTON FOTHERGILL died at his home in Darlington on December 13th, 1915, in his 91st year. He was the senior magistrate of the borough, and was for many years honorary physician to the Darlington Hospital. After studying in Edinburgh he took the diploma of L.R.C.S. in 1850 and the degree of M.D. St. Andrews in 1867; he joined his father in 1848, and remained in active practice for about thirty years. He then partially retired, but continued to work as a consulting physician for another twenty years. Dr. Fothergill took an active part in the civic, philanthropic, and political life of Darlington. He remained strongly Liberal throughout his life. An enthusiastic fisherman, he was constantly seen on the river Tees during the salmon season. In his younger days he was a keen fox-hunter. He was the son of John Fothergill, M.R.C.S., who left his native Wensleydale to practise in Darlington about one hundred years ago. Thus John Rimington was born just about the time when the world's first passenger train began to run between Darlington and Stockton-on-Tees in 1825. He was not a great writer, but he published his personal observations of a case of hydrophobia, and of a case, probably the first, in which he used chloroform in 1848 for the relief of puerperal eclampsia. John Fothergill, the London physician who died in 1780, was a great-great-uncle of the deceased.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Piero Baj, editor of the *Pensiero Medico*; and Dr. Adolphe Blin, professor in the Medical School of Rennes, serving as surgeon-major and head of the temporary hospital No. 30, in that town, aged 63.

Medical News.

On the afternoon of Tuesday, January 18th, a discussion on the treatment of soldier's heart will be opened by Sir James Mackenzie before the Section of Therapeutics and Pharmacology of the Royal Society of Medicine.

At the meeting of the Society for the Study of Inebriety in the rooms of the Medical Society of London, Chandos Street, W., on Tuesday next, at 4 p.m., Mr. John Turner Rae, Secretary of the National Temperance League, will open a discussion on the study of inebriety in the light of two wars.

The usual monthly committee meeting of the Medical Sickness Accident Society was held on December 17th, 1915, with Dr. F. J. Allan in the chair. The reports submitted showed that during the month of November the claims for sickness had risen slightly above expectation, but that for the whole year, so far, the total experience had been below the total expectation. It was reported that new proposals received were greater in number than those for the same period in the preceding year. The number of additional proposals received has been fairly well maintained. One satisfactory feature noted was the increase in the combined sickness and accident and life assurance contracts issued, and the tendency among existing members to avail themselves of the opportunity of increasing their insurances in the society by the addition of endowment life assurances, payable at the age of 65, or previous death. The number of claims from members on active service had, fortunately, been few in comparison with the total number serving in the Royal Army Medical Corps and similar forces. The complete figures will probably be included in the chairman's speech at the next annual general meeting. The soundness of the financial administration of the society during its thirty-three years' of existence is of decided import to members under the present disturbed conditions. The practice of writing down Stock Exchange securities, when necessary, has shown itself to be a wise one, in view of the heavy fall in stock values. It is anticipated that a further sum will have to be written off investments at the close of this year, but practically all the society's holdings are stocks repayable at par at fixed dates. Members of the medical profession would be well advised to avail themselves of the society's insurance against sickness and accident, and any desirous of so doing can obtain all information on application to the Secretary, Medical Sickness and Accident Society, 300, High Holborn.

THE large building known as the Grand Palais, Paris, was early last year converted into a hospital for the physical treatment of sick and wounded soldiers, mainly those suffering from disabling conditions of the limbs. There are separate departments, under medical direction, for baths, electricity, massage movements manual and by apparatus, and for radiology. Dr. Fortescue Fox, who has described this "complementary" hospital in the *Journal of the Royal Army Medical Corps*, states that for stiff and disabled joints and muscles the best results have been obtained by a combined treatment, in which the limb is submitted first to a bath and then to massage and movements. The favourite bath method is by the local hyperthermal bath known as *cau courante*. There is a continual current through the bath, and its temperature can be regulated in a mixer provided with valves. The motion may be that of a gentle stream or a miniature whirlpool. The temperature, checked by the mixer and by a thermometer in the bath, varies from 104° to 122° F., but is usually given as hot as can conveniently be borne for fifteen to twenty minutes daily. The method is said to give results superior to still water at the same temperature, or to the ordinary douche, or hot air or electric radiation baths. The circulation in arteries, capillaries, veins, and lymphatics is stimulated, and there is great vaso-dilatation, but the effect on the nerve endings is sedative. The pain, swelling, and stiffness are diminished, and the mobilization of limbs, either by the hand or by apparatus, is greatly facilitated. The local bath used for the upper limb resembles a small hip bath mounted on a tripod; that for the lower limb, in which the water is admitted at any part of the bath and runs out by a tube at the upper end, is an obliquely-placed cylinder. Recently the bath was being used in 400 cases a day, massage and mechanotherapy in 800, and gymnastic exercises and electrotherapy in 500. We are informed that a hyperthermal bath apparatus is now available in London, and that particulars can be obtained on application to the Secretaries of the committee on the after-treatment of soldiers established by the Balneology Section of the Royal Society of Medicine of London, 1, Wimpole Street, W.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

FERGUSON'S SPECULUM.

GYNAECOLOGIST inquires where the first account of this instrument is to be found. The inventor was, he understands, Dr. W. E. Laing Ferguson, who was in practice in Claremont Square; N., forty years ago, and, according to the *Medical Directory*, died on April 25th, 1880. There is no obituary notice of him in the medical journals of the period nor in the *Transactions* of the Obstetrical Society of London. He must be distinguished from Sir William Ferguson, the eminent surgeon, and Ferguson (one s), the surgical instrument maker in Smithfield.

LACTATION AMONG THE JAPANESE.

A CORRESPONDENT seeks for information as to the usual age at which Japanese children are weaned, and as to what effect, if the age be more advanced than in Europe, the custom has on lactation and pregnancy amongst the women of the race.

* Remy in 1883 wrote: "Among the details of Japanese hygiene I have been especially struck by the manner in which children are fed and brought up. They are suckled by the mother until the age of 5 or 6 years. They run after their mothers asking for the teat in a correct language. The manner in which the age of a child is reckoned may occasion an error of more than a year. However, during a long period the child depends entirely on its mother; artificial lactation is unknown; the mother considers it a duty to suckle her babies." This is a translation of Remy's notes (*Archives gén. de méd.*, vols. i and ii, 1883) by Dr. Albert Ashmead in an article "On the Non-existence of Rachitis in Japan," published in the *New York Medical Record*, vol. xxxviii, October 11th, 1890, p. 399, the author adding a further quotation from Remy: "There is, however, a result of the lactation which I would above all clearly represent. The rachitic (*sic*) does not exist in Japan. I never met him, neither among the children nor among the adults; neither in city, nor in country, nor in hospitals. The physicians, native and foreign, whom I consulted are aware of no single instance."

REBATE ON MOTOR SPIRIT.

HILLMAN made a claim for rebate on motor spirit to the local officer of Customs and Excise some months ago, but has heard nothing of the matter even after repeated reminders. He inquires as to the proper quarter to which any complaint should be addressed.

* The local officers appear to act under the Surveyor of Customs and Excise, whose name and address our correspondent may be able to obtain from the local directory; if the complaint is to go to head quarters the appropriate address would be: The Secretary, Board of Customs and Excise, Customs House, London.

INCOME TAX.

NET INCOME desires information as to the proportion of rent or rental value and other semi-professional expenses deductible for income tax purposes.

* The deduction to be made in respect of rental value is "such sum not exceeding two-third parts... as the Commissioners shall allow" (Sections 100 and 101 of the Income Tax Act of 1842). In most cases the proportion appears to be settled between the person making the return and the surveyor of taxes, but the Commissioners are the authorities for determining the amounts and, where agreement cannot be arrived at, they will decide the question on appeal. Where rents are high it does not necessarily follow that a larger proportion should be allocated to the professional part of the premises, seeing that the whole of the house would be affected by the local conditions of rent. The rental value as assessed includes the ground rent, and that payment does not constitute a separate subject for deduction; if income tax is—as it should be—deducted from the ground rent on payment, then the occupier of the property has not ultimately paid any tax on that portion of the rental assessment which refers to the ground rent. The proportion for dividing the rent

will also apply to the rates and inhabited house duty paid on the premises. The sum to be divided is not an arbitrary estimate of the value but the actual sum upon which income tax has been paid for the year covered by the professional statement of receipts and expenses. There are decided cases which make it quite clear that no deduction can be made by way of sinking fund or otherwise for the expiry of a lease. A payment of income tax is not a deductible expense. The only restriction with regard to the wages of servants, lighting, heating, etc., appears to be that the deductions shall be reasonable having regard to the amounts fairly attributable to professional rather than to private services. No general rule is—or perhaps could be—laid down, the matter being one capable of such wide variation that each case is apparently considered on its own merits. It should not be overlooked that the cost of a servant's food is in effect a part of his or her wages.

LETTERS, NOTES, ETC.

THE Temperance Collegiate Association offers two prizes of 10 and 5 guineas respectively for essays on heredity as a factor in alcoholic degeneration. The characters which the essay should possess can be obtained on application to the Secretary, "Strathblane," Alexandra Park, Nottingham. The Science and Education Committee of the National Temperance League is willing to consider applications addressed to its secretary, Paternoster House, London, E.C., from university and hospital students in physics and medicine for financial assistance in carrying on research or making investigations.

WHOOPIING-COUGH AND KINKHOST.

A CORRESPONDENCE was started recently in *Nature* by an incidental statement to the effect that the word "chincough" meant "hiccough." This was contested by a correspondent, who said that it was applied to whooping-cough in the north of Ireland, and suggested that it might have something to do with the French *chien*, a dog. This rather wild piece of etymology was promptly denounced by more than one correspondent. It was pointed out that "kinkhost" was good and common Scottish for whooping-cough, and that "kink" was used for the paroxysm not only in Scotland but in the north of England, as well as, we believe, in some parts of North America. Other correspondents stated that the term "kinkhoest" was used in Holland and Belgium for whooping-cough, and the similarity to the German "Keuchhusten" was mentioned. Authorities were quoted for the derivation of "kink" from "krik" or "kuk," an imitative word meaning to gasp, which is also the basis of cough. A remark in this correspondence to the effect that *coqueluche*, the French word for whooping-cough, was more puzzling, has brought us an interesting note from Dr. Lawrence Oliphant of Glasgow.

Coqueluche, he writes, is a name transferred from an epidemic disease (resembling influenza or *grippe*) to whooping-cough in recent times. Littré, quoting Ménage, suggests a derivation from *cuculus* through *cuculicchio*, and the word *coqueluche* originally meant a hood or "capuchon." This is borne out by its use as the name of a bird (reed-hunting) with black and white head. A. Paré's use of the word, as also d'Aubigné's, suggests influenza. Rabelais, in the list of books in the Library of St. Victor, has "la coqueluche des moynes," glossed by Lacroix as "rhume et capuchon"—that is, both flu and hood. Smith translates "wheeziness"; Urquhart "cowl or capuchon." In the *Dictionnaire Général*, Hatfield and Darmesteter say that the etymology is unknown, but also give "hood" as the original meaning of the word. In any case, its use as meaning "Kinkhost" is recent, so that the words are probably not related. As to *Keuchen*, Kluge (*Etymologischen Wörterbuch*) seems to make it cognate with English "cough." Mid High German *Kichen*, from Germanic *skik*—that is, sign for root—which in Low German, Netherlandish, and English is nasalized; Holstein, *Kinghosten*; Netherlandish, *Kinkhoest*; M.E., *chincough* for *chink-cough*; compare Swed. *Kikhosta*, Dan. *Kighoste*, Anglo-Saxon *cincung*; in which case our "kinkhost" is just a coughcough!

The fail-me-never Cotgrave (1611) gives "Coqueluche, f., a hood; also the Coqueluchoe, or new disease; which troubled the French about the yeares 1510 and 1557, and us but a while agoe." Ménage (1650) also gives information about the epidemics and the use of the word "coqueluche" from 1414 onwards.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	---	---	0 5 0
Each additional line	---	---	0 0 8
A whole column	---	---	3 10 0
A page	---	---	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE BACTERIA OF GANGRENOUS WOUNDS.*

BY

MAJOR H. R. DEAN, M.D., F.R.C.P., R.A.M.C.(T.),

PROFESSOR OF PATHOLOGY, UNIVERSITY OF MANCHESTER,

AND

CAPTAIN T. B. MOUAT, M.D., F.R.C.S., R.A.M.C.(T.),

3RD NORTHERN GENERAL HOSPITAL, SHEFFIELD.

(Report to the Medical Research Committee.)

THE cases which provided the material for this investigation were selected from those undergoing treatment at the 3rd Northern General Hospital, Sheffield. The injuries were of a severe nature, and in nearly all there was evidence of the presence of necrotic or gangrenous tissue in the wound. Comparatively few, however, presented the clinical features of emphysematous gangrene.

Methods Employed.

The material used for examination consisted of fragments of necrotic tissue or of the discharges from the deeper parts of the wound.

The procedure usually adopted was as follows: Films were prepared and stained by various methods. Attention was directed to the cells and to the appearance and numbers of bacteria present in the discharge.

Methods for the Isolation of Aërobic Organisms.

Plate cultures were made on blood agar, and in some cases on MacConkey's medium. The resulting colonies were identified by the usual methods.

Methods for the Isolation and Identification of Anaërobic Organisms.

A tube containing about 5 c.cm. of broth was heavily inoculated with the material to be examined. In some cases a small piece of necrotic tissue was placed bodily into the tube, in others the material present on one or two swabs was thoroughly emulsified in the broth. In place of broth the following medium was employed on several occasions.

"Egg Broth."

The white and yolk of one egg were thoroughly beaten up by vigorous shaking in a stout glass bottle containing a liberal supply of glass beads; 300 c.cm. of distilled water were then added, and the mixture was thoroughly shaken. The bottle containing the mixture was then placed in a water bath which was slowly brought to the boil. This temperature was maintained for half an hour. During the whole period of heating the bottle was constantly and violently shaken. The result was a loose porridge-like mass consisting of finely divided particles of egg suspended in fluid. The medium was distributed in quantities of 50 to 100 c.cm. in wide-mouthed bottles, which were plugged and sterilized in the autoclave.

"Egg broth" prepared in this way proved to be very useful as a culture medium for the growth of anaërobic micro-organisms. It is particularly useful for the growth of *B. oedematis maligni*.

This egg broth or ordinary nutrient broth, after liberal inoculation, was heated for half an hour at a temperature of 80° C. It was then incubated in a Bulloch's chamber at 37° C. for periods which varied from two to twenty days. After this preliminary incubation (1) films were prepared, stained, and examined; (2) guinea-pigs were inoculated subcutaneously with one or two cubic centimetres of the broth; (3) agar, blood agar, or glucose agar plates were prepared, inoculated from the broth, placed in a Bulloch's chamber, and incubated for a period of three to seven days.

It was found that glucose agar was the most suitable medium for these anaërobic plate cultures. Subcultures from the resulting colonies were made on Dorset's egg medium, which proved admirably adapted for the needs of *B. aerogenes capsulatus* and *B. oedematis maligni*. It is probably better to subculture tetanus on glucose agar. The cultural characteristics of the various strains of anaërobic bacteria were examined on various culture media.

* A more detailed account of this investigation is to be published in the Journal of the Royal Army Medical Corps.

Comment on Results.

The eighteen cases enumerated in Table I came under observation during a period of ten months from September, 1914, to June, 1915. The patients had been wounded in various parts of France and Belgium during this period. Although the number of cases is small, the series comprises patients wounded in widely separated districts and under very different climatic conditions, and in the circumstances the absence of variety in the bacteriological findings is somewhat noteworthy. The cases investigated were those in which there had been gross destruction of tissue, with subsequent necrosis and gangrene. The discharge from the wound was, in the majority of cases, excessively offensive.

The aërobic bacteria which were isolated call for little comment. Streptococci were isolated from nearly every case. No attempt was made to define accurately the variety of streptococcus, but nearly all those isolated appeared to belong to one type, which in films appeared as a small diplococcus, or more rarely as a chain of four or six members. It grew freely on blood-smear agar and on ordinary agar in small translucent colonies. Films made from blood agar cultures showed short chains. Staphylococci were isolated less frequently than might have been anticipated. When present, they were not as a rule numerous.

B. coli was only isolated from four cases. The only other aërobic organism of any interest was a *proteus* bacillus from case No. 5.

The Anaërobic Bacteria.

Only three varieties of anaërobic bacteria were isolated—the *B. aerogenes capsulatus*, *B. oedematis maligni*, and the *B. tetani*.

These varieties belong to one group of bacteria, whose normal habitat is usually stated to be highly cultivated earth and dung; their constant presence in wounds of the type investigated was to be anticipated.

Morphology and Staining Reactions.

B. aerogenes capsulatus and *B. oedematis maligni* differ enormously both in shape and in staining reactions under different cultural conditions, and the identification of either from the appearances seen in a film preparation alone may often be difficult. The results obtained by Gram's method of staining differ greatly with the nature of the culture medium and the age of the culture. The influence of the variety of culture medium employed on the formation of spores is also well marked.

The relative rate of growth of the different varieties is a matter of some interest from the practical standpoint, and

is a factor which must be allowed for in any attempt to isolate bacteria of this group in pure culture. In a mixed culture made by inoculating a tube of broth with the discharge obtained from a wound the different varieties appear after different periods of time, as it were in crops. After two or three days' incubation the broth may appear to contain a pure culture of *B. aerogenes capsulatus*. After a further period of incubation the *B. oedematis maligni* is often the predominant organism. Tetanus bacilli seem to require a still longer interval for multiplication, and may appear first after ten days' incubation. A result of this kind was obtained on several occasions, and in the later cases of the series the original broth culture was subjected to a routine examination at various intervals after inoculation. The preparation of pure cultures was thereby considerably facilitated. It is possible that a similar method might prove useful in dealing with other groups of bacteria.

The cultural characteristics of the various strains were examined on a variety of media. The appearances of well isolated colonies on agar and glucose agar plates, the characteristics of the growth on agar, glucose agar, broth, litmus milk and Dorset's egg medium, and the reactions produced with various sugars and alcohols were recorded.

THE BACILLUS OF MALIGNANT OEDEMA.

A pure culture of this bacillus was isolated in fifteen of the eighteen cases. All were cases in which considerable laceration and necrosis of tissue had occurred, and all were characterized by an offensive discharge. The degree and extent of the septic process varied considerably in the various cases of the series. Gas formation in the tissues was observed in four cases only, in three of which *B. aerogenes capsulatus* was also found. Of the fifteen cases three only were fatal—Cases 2, 16, and 17. In Case 2 there was a large gas-containing abscess of the arm, *B. aerogenes capsulatus* and *B. coli* were also present. Case 16 was one of tetanus. Case 17 was remarkable in that it was the only case of the series in which, although there was abundant gas formation in the tissues, *B. aerogenes capsulatus* was not found. Twelve cases of the fifteen in which *B. oedematis maligni* was found made good recoveries. There is apparently no reason to think that the presence of this micro-organism in a wound is necessarily of serious import. This conclusion is substantiated by the results obtained by the inoculation of animals. Its presence is an indication of the occurrence of gangrene, for it has probably little or no capacity for multiplication in living tissue. There appears to be no evidence that its presence is constantly associated with any particular group of signs or symptoms. Many of the films prepared from pus showed that this bacillus is readily taken up by the polymorphonuclear leucocytes.

Isolation of Pure Cultures.

The bacillus of malignant oedema grows extremely well on egg media. When but few are present in the discharge pure cultures are most readily obtained by freely inoculating the egg broth described in an earlier part of this paper and incubating in an anaërobic chamber for five to seven days. The *B. oedematis maligni* may then often be found in very large numbers and pure cultures may readily be obtained by plating on glucose agar.

Cultural Characteristics.

The appearances of a slope culture on Dorset's egg medium are very characteristic. A profuse creamy white growth appears within twenty-four hours. It increases rapidly and is at first raised above the surface of the medium. At the end of forty-eight hours, or even earlier, liquefaction is noticed. A clear fluid gradually accumulates in the lower part of the tube, in which float drops of oil. Liquefaction continues rapidly, and a bluish-black discoloration is a well-marked characteristic of *B. oedematis maligni* in this medium. The odour is extremely powerful and offensive; it is somewhat suggestive of gorgonzola cheese.

Films made from such a culture after incubation at 37° C. under anaërobic conditions for three days showed the following characteristics: The bacilli varied greatly in length; the larger forms, which were the more

numerous, were from 8 to 10 μ long and 0.6 μ wide. Of the shorter forms several were observed which measured about 2 μ in length and 0.6 μ in width. The majority of the bacilli occurred singly, but chains of two, four, and six members were met with. They were Gram-positive. Many of the bacilli contained spores which were of an oval shape and situated near to one end of the bacillus. Occasionally one bacillus appeared to contain two spores. A contained spore of average size measured 1.5 μ by 1 μ . There were also a comparatively small number of free spores approximately 2 μ long by 1 μ wide. Films made from an egg culture after seven days' incubation showed numerous large, free oval spores, but very few bacillary forms. The bacilli present in these old egg cultures were Gram-negative.

Surface colonies on glucose agar plates showed a central opaque node from which radiated numerous long delicate hair-like processes. Streak cultures on glucose agar slopes showed a central opaque whitish line, with delicate hair-like lateral projections. Stab cultures in deep glucose agar tubes are not characteristic. Gas formation is well marked, but usually less than in cultures of *B. aerogenes capsulatus*. Profuse growth occurs along the deeper portions of the needle track. The lateral projections are seldom slender spikes, but more often in the form of disc or coin-shaped, circular, flattened projections. Very similar appearances are seen in stab cultures of *B. aerogenes capsulatus*.

Microscopical Appearances of Films made from a Glucose Agar Slope after Three Days' Incubation at 37° C., under Anaërobic Conditions.

The majority of the bacilli were Gram-negative. Variation in size was even more marked than in the case of the egg culture. The following dimensions, which are fairly representative, may be given:

Length	...	15 μ	Breadth	...	0.6 μ
"	...	8 μ	"	...	0.8 μ
"	...	3 μ	"	...	1.5 μ

Some of the shorter forms resembled oval cocci in outline. The majority were short single rods with rounded ends. There were also long chains of slender bacilli constituting delicate filaments, in which the subdivisions could be distinguished with difficulty or not at all. Spores were not found. After eight days' growth on glucose agar the appearances were not greatly different. All bacilli were Gram-negative and stained poorly. There were great variations in length. A few spores were seen.

The appearances of surface colonies on agar plates, slope cultures, and in deep stabs are similar to those observed with glucose agar. The growth is less profuse. The microscopical appearances of films from an agar slope after three days' incubation were similar to those seen in films made from the glucose agar culture of the same age. Spores, however, were fairly numerous. After eight days' growth on agar the films showed numerous short forms containing spores and a large number of free spores. The bacteria stained badly, and were Gram-negative.

On broth rapid growth occurred with the production of turbidity and an offensive odour. After about a week a deposit formed at the bottom of the tube. In broth cultures filamentous forms or chains were frequent, and attained a considerable length. Spore formations occurred readily, and the older cultures contained more spores than bacillary forms. In young broth cultures the majority of forms were Gram-positive, in older cultures Gram-negative.

After incubation in litmus milk for about seven days under anaërobic conditions very characteristic changes may be observed. When the anaërobic chamber is first opened the contents of the tube are seen in two layers. The upper layer is turbid but translucent, the lower layer consists of a bulky dirty white deposit. The odour is sour and offensive. If the culture is allowed to stand on the bench for twenty-four hours, colour returns to the upper layer. There are now three well defined layers. The uppermost layer has a reddish claret colour except at the actual air surface, where a poorly marked blue ring may often be seen. The middle layer is a colourless translucent, but slightly turbid, fluid. At the bottom of the tube is a bulky deposit. On shaking the tube the whole of the contents assume a claret colour. The fluid is amphoteric to litmus paper.

On inspissated serum a whitish growth appears, and the medium is slowly liquefied with the formation of a neutral or faintly alkaline fluid. There is no discoloration, but the odour of the culture is offensive.

B. oedematis maligni ferments glucose and maltose with the formation of acid and gas. Its action on these sugars is less rapid and less violent than that of *B. aerogenes capsulatus*. Some strains act very slowly, others show a well-marked acid reaction within forty-eight hours. Cane sugar, lactose, mannite, and dulcitol remain unaltered. After seven days' incubation under anaërobic conditions the appearance of a tube of serum water glucose or maltose is as follows: At the bottom of the tube is a considerable deposit consisting of flocculi and shreds of torn-up clot. The supernatant fluid is colourless and slightly turbid. At the surface a few shreds of clot of a bright red colour may be seen floating. On shaking, the entire contents of the tube assume a red colour. The culture has an odour suggestive of lactic acid. In the case of some of the strains of malignant oedema, the reaction of the glucose and maltose cultures after incubation was only slightly acid, and no clot was formed. In the majority of cases the sugar reactions were recorded shortly after the isolation of the pure culture, and the tests were repeated after the strains had been subcultured for several months. The strain isolated from Case 3 gave the same reactions in June as it had done shortly after isolation in the previous December.

B. AEROGENES CAPSULATUS.

This bacillus was isolated from 13 of the 18 cases. In all but one (No. 13) the bacillus of malignant oedema was also found. It was present in 3 of the 4 cases in which the presence of "tetanus" bacilli was demonstrated. It was present in 3 of the 4 cases in which signs of tetanus developed in the patient. It was present in 3 of the 4 cases in which gas was present in the tissues. Of the 13 cases only 2 were fatal, and in one of these death was due to tetanus.

Isolation.

This bacillus grows readily in broth and egg broth under anaërobic conditions. If the mixed culture which is prepared from the discharge be examined after forty-eight hours, large numbers of this bacillus are often found, and a pure culture may readily be obtained by plating on glucose agar.

Morphological and Cultural Characteristics.

In films made from the fluid present in the subcutaneous tissues of a guinea-pig which has succumbed to experimental inoculation, numerous short Gram-positive rods are seen. The majority occur singly, and have square ends. The organism also occurs in pairs and chains of four. A capsule can be demonstrated. Many of the bacilli are seen within leucocytes. In some of the films made from the pus obtained from gangrenous wounds similar short definitely Gram-positive bacilli occurred. There were, however, other forms, somewhat larger, which stained unevenly by Gram's method. These bacilli exhibited a peculiar arrangement of Gram-positive stripes or granules on a Gram-negative ground. Both these and the Gram-positive forms were encapsulated.

B. aerogenes capsulatus grows excellently on Dorset's egg medium, although not so vigorously as does the bacillus of malignant oedema. The colonies are white, circular, and at first raised above the surface. After three or four days the medium is slowly eroded, and the colonies come to lie at the bottom of shallow saucer-like depressions. The digestion of the medium proceeds slowly, but nothing like the rapid liquefaction produced by *B. oedematis maligni* is seen. No discoloration of the medium occurs. Films prepared from a 48 hours' slope culture on Dorset's egg medium showed single short Gram-positive rods of fairly uniform length. There were a few long and comparatively slender forms and a few very short forms which resembled cocci. Spore formation occurs on this medium. The spores, which are oval in shape, distend the central portion of the bacillus, the remaining cytoplasm of the bacillus appearing as two caps, one at either end of the bacillus. Films prepared from old egg cultures showed great varieties in shape, size, and reaction to Gram's stain. Spores were numerous. On films made from egg medium long slender bacilli with a round

terminal spore are occasionally met with. These forms closely resemble the tetanus bacillus.

Isolated colonies on the surface of agar and glucose agar medium appear to the naked eye as circular colonies, 1 to 4 mm. in diameter, somewhat opaque, whitish in colour, and definitely thicker in the centre. Viewed under a $\times 10$ lens, the centre of the colony is seen to be opaque and raised up above a thin semitranslucent marginal zone, which often shows several rings. The margin is slightly wavy, and occasionally the irregularities of the outline are so well marked that an appearance of short offsets or processes is produced. Streak cultures on the surface of a glucose agar slope show a central opaque white line and a marginal somewhat translucent zone, which has a wavy outline. In glucose agar slabs the evolution of gas is commonly so violent that the wool plug and the greater part of the culture medium are expelled from the tube. Under less violent conditions the growth appears as an opaque white streak along the track of the needle, from which proceed flat coin-like outgrowths. The appearances of surface colonies on agar are similar to those on glucose agar, except that the growth is less vigorous. Films prepared from agar and glucose agar cultures of the same age show very marked differences. In films made from a 48 hours' agar culture short forms predominate. Many of the bacilli are very short, very broad, and present an almost square outline. Clostridial forms occur. The margins of many of the bacilli are indistinct and blurred. The bacilli occur singly. Both Gram-positive and Gram-negative forms may be found, but many show well-marked Gram-positive markings on a Gram-negative ground. Films prepared from a 48 hours' glucose agar culture showed considerable varieties in the length of individual bacilli, but long forms predominated. There were numerous pairs and short chains, and a few long chains of six, eight, or more bacilli. In older glucose agar cultures numerous club-shaped forms occurred. In neither agar nor glucose agar cultures were spores found.

Broth cultures are in no way characteristic. Uniform turbidity is seen in young cultures. Older cultures show a deposit and a comparatively translucent supernatant fluid. Films prepared from broth cultures showed numerous short broad rods. The majority occurred singly, but pairs and short chains were not uncommon.

On inspissated serum a greyish-white, not very profuse, growth makes its appearance. The surface of the medium is very slowly eroded. Films show forms similar to those seen in films prepared from egg medium. Spore formation occurs on this medium. Forms resembling the tetanus bacillus are occasionally met with.

The appearances of a litmus milk culture are well known. The production of acid and the formation of a clot are accompanied by a violent evolution of gas. After three or four days the tube is found to contain a clear acid translucent fluid and fragments of gas-contorted clot.

Sugar Reactions.—Violent fermentation occurs in media containing glucose and maltose with production of acid and much gas. Cane sugar and lactose are much less readily attacked, and the reaction in media containing these sugars is less acid. No reaction takes place with mannite, dulcitol, and inulin. The reactions can be demonstrated by the use of the ordinary peptone-sugar media or by Hiss's serum water sugar media. In the latter media the production of acid is accompanied by the formation of a clot, the disruption of which affords satisfactory evidence of the evolution of gas. The torn and lacerated clot, and the clear, strongly acid fluid which are found in the serum maltose tubes and serum glucose tubes present very characteristic appearances. The sugar reactions of *B. aerogenes capsulatus* were found to be quite constant, and were the same in all the strains examined.

INOCULATION EXPERIMENTS.

The results obtained by the inoculation of the mixed growth contained in the original broth cultures yielded very variable results.

Inoculation experiments were undertaken with eight strains of *B. oedematis maligni* and with five strains of *B. aerogenes capsulatus* in pure culture. In the first series of experiments the inoculated material consisted of either a broth culture, or an emulsion in broth of several loopfuls of the surface growth from a Dorset's egg or agar slope. The injections were subcutaneous. Thirteen

guinea-pigs and two rabbits were inoculated with cultures of *B. oedematis maligni*. One of these animals died twenty-four hours after inoculation. The cause of death, which could not be ascertained, was probably not the inoculation, for the site of the injection showed only a slight inflammatory reaction. The remainder of the animals survived and remained in good health for one month after the inoculation. In a few cases there were signs of illness during the first forty-eight hours, and examination revealed a slight swelling at the site of inoculation. Recovery was in these cases rapid and apparently complete. In the first series of experiments with *B. aerogenes capsulatus* twelve guinea-pigs and two rabbits were used.

Two guinea-pigs which had been inoculated subcutaneously at 5 p.m. on November 25th with 2 c.cm. of a broth culture of *B. aerogenes capsulatus* from Case 2, were found dead at 9 a.m. on November 26th. Emphysema was found at site of inoculation and the skin had been separated from the deep tissues over the greater part of the trunk. The subcutaneous tissues were infiltrated by a blood-stained fluid, in which floated globules of fat. Gas was present in the subcutaneous tissues, but not in the organs of the thorax and abdomen. Films made from the site of inoculation contained large numbers of *B. aerogenes capsulatus*, and a pure culture of this bacillus was obtained from the exudate. The heart blood was sterile.

On December 11th a guinea-pig received a subcutaneous injection of 1 c.cm. of a broth culture of the same strain (Case 2). The animal was found dead on December 15th. Necrosis of tissue was found at the site of the injection, and films showed *B. aerogenes capsulatus* and numerous streptococci. All the organs of the body and the serous membranes were engorged with blood. The lungs showed patchy consolidation. Films made from the lung showed streptococci only. The heart blood was sterile.

On December 11th a guinea-pig received a subcutaneous injection of 1 c.cm. of a broth culture of *B. aerogenes capsulatus* (Case 3). Slight local swelling and gas formation followed. The animal had apparently completely recovered after forty-eight hours. It died on December 18th. At the post-mortem examination an acute volvulus of the small intestine was found.

In two additional experiments with pure cultures from strain No. 2 the animals remained in perfect health for two months. Similar experiments were performed with pure cultures from Cases 10, 12, 13, and 14. In each case two guinea-pigs were inoculated. One of the animals inoculated with Strain 13 died after twenty-four hours from typical gas gangrene. The remaining seven animals were kept under observation for more than a month and showed no evidence of infection.

Two rabbits received a subcutaneous injection of 2 c.cm. of a pure culture of Strain 2. After twenty-four hours there was a slight local swelling and the animals appeared to be slightly unwell. Recovery had taken place at the end of forty-eight hours and no further symptoms were observed.

The conclusion arrived at from these experiments was that the subcutaneous injection of pure cultures of *B. aerogenes capsulatus* may occasionally give rise to fatal gas gangrene. With possibly one exception, all the experiments with pure cultures of *B. oedematis maligni* yielded negative results.

The results obtained by animal inoculation with pure cultures accord well with the evidence afforded by the clinical findings in the various cases above recorded. Both *B. oedematis maligni* and *B. aerogenes capsulatus* were present in the majority of the cases; but three only of the eighteen patients died, and in four cases only was gas formation observed in the tissues. We must assume that neither of these micro-organisms is truly parasitic—that is to say, neither bacillus is capable of multiplication in living tissue. In blood clot, in dead tissue, and fragments of foreign bodies which are so often present in wounds, they are capable of active growth and multiplication. Here they produce, by ferment action, poisonous substances, possibly organic acids,* which, in circumstances favourable to them, diffuse out into the surrounding living tissue. The result is that the adjacent tissues die and are then invaded by the micro-organisms. In this fashion the gangrenous area increases in size, successive zones of tissue being first poisoned and then invaded by the saprophytes.

Acting on the assumption that the pathogenic action of these micro-organisms might be dependent on the action

of the organic acids which they produce, the following experiments were undertaken:

B. oedematis maligni (Strain 3) and *B. aerogenes capsulatus* (Strain 2) were subcultured on agar, broth, Dorset's egg medium, and on serum water, cane sugar, glucose, lactose, maltose, mannite, and dulcitol. With *B. aerogenes capsulatus* marked acid reactions were obtained with glucose and maltose, and less marked reactions with cane sugar and lactose. With *B. oedematis maligni* the media containing glucose and maltose became slightly acid. A portion of each medium was injected into a guinea-pig. In the case of the fluid media the quantity inoculated was 2 c.cm.; in the case of the solid media one loopful of the growth was emulsified in 2 c.cm. of broth. It was thought that the cultures which contained acid might prove the more pathogenic. The result of the experiment was negative. In no case was gangrene produced, and, with the exception of slight and transient symptoms, all the animals remained in perfect health. In a third series of experiments guinea-pigs were inoculated with various strains of *B. oedematis maligni* and *B. aerogenes capsulatus* mixed with a recently isolated strain of *Staphylococcus aureus*. It was thought that the anaerobic bacteria might gain a hold in the tissue damaged by the action of *Staphylococcus aureus*.

INOCULATION EXPERIMENTS.

Series 3.

Experiment 1.—*B. oedematis maligni*, Strain 8, alone. Inoculated on May 27th. No symptoms. Animal alive and well on July 1st.

Experiment 2.—*B. oedematis maligni*, Strain 8, + *Staphylococcus aureus*. Inoculated on May 27th. No symptoms. Animal alive and well on July 1st.

Experiment 3.—Same as Experiment 1.

Experiment 4.—*B. oedematis maligni*, Strain 8, + *Staphylococcus aureus*. Inoculated on May 27th. Animal ill, with local swelling, on May 29th. Died on June 2nd; gangrene of subcutaneous tissues, blood-stained rancid effusion. Films showed pus cells, cocci, and *B. oedematis maligni*.

Experiment 5.—Same as Experiment 1.

Experiment 6.—*B. oedematis maligni*, Strain 8, + *Staphylococcus aureus*. Inoculated on May 27th. No local symptoms. Died on June 14th. No lesion at site of inoculation. No obvious cause of death.

Experiment 7.—*B. oedematis maligni*, Strain 2, alone. Inoculated on May 27th. Died on June 12th. No local lesion; no obvious cause of death.

Experiment 8.—*B. oedematis maligni*, Strain 2, + *Staphylococcus aureus*. Inoculated on May 27th. Died the following day. Swelling and oedema at site of inoculation. Film showed numerous cocci and *B. oedematis maligni*.

Experiment 9.—*B. oedematis maligni*, Strain 15, alone. Inoculated on May 27th. No symptoms. Alive and well on July 1st.

Experiment 10.—*B. oedematis maligni*, Strain 15, + *Staphylococcus aureus*. Inoculated on May 27th. Died on June 21st. No local lesion; no obvious cause of death.

Experiment 11.—Same as Experiment 9.

Experiment 12.—*B. oedematis maligni*, Strain 15, + *Staphylococcus aureus*. Inoculated on May 27th. On May 29th there was local swelling, which was marked on the following day; animal very ill. On the 31st it was much better. It eventually recovered, and was quite well on July 1st.

Experiment 13.—*B. aerogenes capsulatus*, Strain 2, alone. Inoculated on May 27th. On the 28th there was local swelling, and the animal was ill. On the 29th the swelling had disappeared, and the animal was well. It recovered completely, and was alive and well on July 1st.

Experiment 14.—*B. aerogenes capsulatus*, Strain 2, + *Staphylococcus aureus*. Inoculated on May 27th. On May 29th there was local swelling; animal slightly unwell. It recovered completely, and was alive and well on July 1st.

Experiment 15.—*B. aerogenes capsulatus*, Strain 3, alone. Inoculated on May 27th. Died on June 18th. No local lesion; no obvious cause of death.

Experiment 16.—*B. aerogenes capsulatus*, Strain 3, + *Staphylococcus aureus*. Inoculated on May 27th. No symptoms. Animal alive and well on July 1st.

Experiments 17 and 18.—Controls: *Staphylococcus aureus*, alone. Inoculated on May 27th. No symptoms. Animals alive and well on July 1st.

The results obtained in the above series of inoculations were not very conclusive. Possibly a more interesting result might have been obtained by the use of a more virulent culture of *Staphylococcus aureus*. Of the eighteen animals, two died with typical gangrene around the site of inoculation. Both of these animals (No. 4 and No. 8) had been inoculated with a mixture of *B. oedematis maligni* and *Staphylococcus aureus*. The control animals (No. 3 and No. 7), which were inoculated with the same strains of *B. oedematis maligni* and *Staphylococcus aureus*,

* After our paper had been sent to press there appeared in the BRITISH MEDICAL JOURNAL of December 4th a Note on a Supposed Soluble Toxin, Produced in Artificial Culture by the Bacillus of Malignant Oedema, by G. Barger and H. H. Dale. These workers have been able to prove that the "poisonous substances," the presence of which we suspected, are ammonium salts. The well-marked proteolytic activity of *B. oedematis maligni* is referred to in our paper.

did not develop gangrene. On the other hand, two other guinea-pigs (No. 2 and No. 6), which were inoculated with a mixture of *Staphylococcus aureus* with the same strain of *B. oedematis maligni* as was used in Experiment No. 4, did not develop gangrene. In the case of several of the patients reported in this series pieces of clothing were removed from the depth of the wound. It is presumed that such fragments, which must be often covered with mud and impregnated with anaërobic bacteria or their spores, may often form the starting-point of gangrene.

In the following four experiments an attempt was made to reproduce these conditions by the introduction of a foreign body heavily charged with anaërobic bacteria. Splinters about $\frac{1}{4}$ in. long were prepared from wooden matches and impregnated with cultures of *B. aërogenes capsulatus* and *B. oedematis maligni*. They were then introduced into the subcutaneous tissues of guinea-pigs.

INOCULATION EXPERIMENTS.

Series 4.

Experiment 1.—*B. oedematis maligni*, Strain 8. Splinter inserted on June 26th. The animal was well on June 28th. Marked swelling developed around the splinter on the 29th, and on the 30th the animal was very ill. It subsequently recovered completely.

Experiment 2.—*B. oedematis maligni*, Strain 8. Splinter inserted on June 26th. On June 28th there was marked swelling around the splinter; animal ill. It died the following day. Inflammation and oedematous infiltration around splinter.

Experiment 3.—*B. aërogenes capsulatus*, Strain 2. Splinter inserted on June 26th. The animal was well until June 30th, when marked swelling developed around the splinter. Animal very ill, but subsequently recovered completely.

Experiment 4.—*B. aërogenes capsulatus*, Strain 2. Splinter inserted on June 26th. No symptoms developed.

The series of inoculation experiments with these strains of *B. oedematis maligni* and *B. aërogenes capsulatus* led to the following conclusions:

1. The subcutaneous injection of pure strains does not, as a rule, produce any sign or symptom of disease.
2. If the tissues are damaged by a parasitic micro-organism, foreign body, or other irritant, the introduction of *B. aërogenes capsulatus* or *B. oedematis maligni* may, in a comparatively small number of cases, lead to local gangrene and the death of the animal.

TETANUS.

No. of Case.	Symptoms of Tetanus in Patient.	Prophylactic Injection of Antiserum.	Presence of <i>B. tetani</i> Proved by Inoculation.	No. of Days required for Bacteriological Diagnosis.	Other Anaërobic Bacteria Present.
No. 1	+	■	■	—	<i>B. oedematis maligni</i> . <i>B. aërogenes capsulatus</i> .
No. 6	+	0	+	19	<i>B. oedematis maligni</i> .
No. 10	0	+	+	6	<i>B. oedematis maligni</i> .
No. 14	■	+	+	15	<i>B. oedematis maligni</i> . <i>B. aërogenes capsulatus</i> .
No. 15	+	0	0	—	<i>B. oedematis maligni</i> . <i>B. aërogenes capsulatus</i> .
No. 16	+	0	+	13	<i>B. aërogenes capsulatus</i> .

The methods which were employed with the object of establishing a bacteriological diagnosis of tetanus fall under three headings:

1. The microscopical examination of (a) films from the discharge from the wound, (b) films from the original mixed culture prepared by the inoculation of broth with the discharge.
2. The inoculation of guinea-pigs with the original mixed culture.
3. The isolation of *B. tetani* in pure culture.

1. Examination of Films.

In none of these cases were bacteriological forms resembling *B. tetani* found in films made from the discharge. In the films made from mixed broth cultures tetanus forms were observed in Cases 6, 10, 14, and 16, and also in Case 1. By the expression "tetanus form" is implied a slender

Gram-positive rod bearing a large absolutely terminal round spore. Microscopical examinations of films from the original broth culture of Case 15 were made on numerous occasions, but no forms resembling tetanus were observed.

In Cases 6 and 16 tetanus forms could not be demonstrated until the mixed culture had been incubated under anaërobic conditions for a relatively long period. Unfortunately no systematic attempt was made to record the number of days which elapsed in each case before bacteria resembling tetanus appeared in the broth cultures.

The following observations were, however, recorded:

	Tetanus Forms not present after			Tetanus Forms present after		
Case 1	—	2 days
Case 6	6 days	17 days
Case 10	—	4 days
Case 14	3 days	8 days
Case 16	5 days	10 days

It appears that:

1. Tetanus bacilli are often not found in films made from the discharge from the wound.
2. A long time may elapse before they appear in cultures in sufficient number for microscopical recognition.

A more serious objection to the microscopical method of diagnosis is the fact that closely similar, if not indistinguishable forms, occur in films made from pure cultures of *B. oedematis maligni* and *B. aërogenes capsulatus*. On the other hand, a pure culture of *B. tetani* may often contain many bacilli which are in no way characteristic in appearance. In the absence of other evidence, the discovery of tetanus-like bacilli in films is not satisfactory evidence of the presence of *B. tetani*. The presence in a film of numerous slender Gram-positive bacilli, bearing a large round terminal spore, is, of course, a suspicious circumstance, and may justify a preliminary opinion. The microscopical evidence is, however, not sufficient, unless supported by the result of an inoculation experiment.

2. Inoculation of Mixed Broth Culture.

The presence of *B. tetani* was demonstrated in Cases 6, 10, 14, and 16 by injecting a guinea-pig with the original mixed broth culture.

One or two cubic centimetres of the culture were injected beneath the skin on the left side of the chest. After a variable interval—usually two or three days—slight stiffness of the forelimb nearest to the site of inoculation was observed. Within a few hours the limb became rigid in a position of extreme extension. Subsequently a condition of extensor spasm spread to the other limbs and the muscles of the neck and back. Death usually occurred within twenty-four to forty-eight hours after the first onset of symptoms. In the majority of cases there was little or no evidence of inflammation at the site of inoculation. The method is a satisfactory one, and yields results which are not open to doubt. The disadvantage is the considerable interval that may elapse before a demonstrable amount of toxin is produced.

3. Isolation of Pure Cultures.

In Cases 6, 10, 14, and 16 tetanus bacilli were found in large numbers in the original mixed broth cultures, and the inoculation of these broth cultures produced characteristic symptoms in animals. In only one of these cases was the tetanus bacillus isolated in pure culture, in the other three cases repeated attempts ended in failure. Agar, glucose agar, and blood agar plates were employed; colonies of *B. oedematis maligni* were readily obtained, but not of tetanus. Fractional heating was employed in the hope that the spore of tetanus might prove more resistant than that of malignant oedema. No success was obtained in this way. A pure culture was eventually obtained by the inoculation of glucose agar plates with the mixed broth culture from Case 16.

Cultural Characteristics.

The surface colonies on glucose agar plates varied greatly in size. They were round, opaque, and rather white. Under a hand lens they showed a central portion which was thicker and made up the greater part of the colony, surrounded by a thin, translucent margin, which had a wavy outline.

With higher magnification the centre of the colony was seen to be granular, while the margin showed delicate rounded projections. In older cultures numerous small circular opaque nodes or thickenings appeared on the colony. These may perhaps be described as secondary colonies. Other colonies showed large branching out-growths, which were beautifully rounded, and somewhat suggested the contour of an oak-leaf. Streak cultures on glucose agar slopes showed a central thick opaque line and a broad, translucent margin, showing branching and rounded processes. The appearance of agar cultures was similar, but the growth was not so vigorous. Broth cultures became turbid with the formation of a deposit. The growth on Dorset's egg medium was not very vigorous, but resembled that on glucose agar. Flat white colonies appeared, which after a time came to lie in shallow depressions in the medium. No change was produced in litmus milk. The sugar reactions were examined on several occasions with Hiss's serum water, and with peptone water media. This strain produced no change on cane sugar, glucose, maltose, lactose, mannite, dulcitol, and inulin.

The microscopical appearances of films from various culture media were recorded. As only one strain was examined, the results have little value.

The appearance of bacilli grown on agar, glucose agar, and broth accorded with the description usually given of this micro-organism. The bacilli were slender, showed considerable variations in length and size, and had rounded ends. The majority occurred singly. Many bacilli contained spores, the majority of which were terminal, round, and very large. In a very few bacilli the spores were oval in shape and were either in the centre of the bacillus or near but not actually at one end. These forms showed a close resemblance to the appearances commonly met with in cultures of *B. oedematis maligni*. In a few of the bacilli there was an appearance of granules similar to that seen in films of *B. aerogenes capsulatus*. Bacilli which appeared to have two terminal spores occurred occasionally. Films made from a three days old culture on Dorset's egg medium were distinctly different in appearance. The majority of the bacilli appeared to be broader than those grown on agar. Although in many bacilli the spore was terminal, there were many others in which it was oval and occupied a central position. Apart from the spore-bearing forms, bacilli occurred in which the poles stained faintly, while the centre appeared as a solid deeply stained band. In other bacilli the arrangement was reversed, and a bipolar effect was produced. Possibly these appearances represent early stages of spore formation.

Inoculation Experiments.

Eleven guinea-pigs and 2 rabbits were inoculated from a ten-day-old pure broth culture of this strain. Tetanus developed in 4 of the guinea-pigs. The other 7 guinea-pigs and the 2 rabbits showed no evidence of the disease.

Remarks on above Cases of Tetanus.

It is perhaps worthy of note that the two patients who did not suffer from tetanus although the presence of tetanus bacilli was demonstrated in the wounds had received a prophylactic injection of antitoxin. The four patients who developed signs of tetanus did not have a prophylactic injection. In Cases 10, 14, 15, and 16, fragments of clothing were removed from the wound. It may be assumed that the presence of fragments of cloth, saturated with the discharges of a gangrenous wound, must form a peculiarly suitable nucleus for the growth of tetanus bacilli.

The results above recorded lead to the conclusion that the microscopical examination of films made from the discharge from a wound may be of little value in the diagnosis of tetanus. Satisfactory results may be expected from the injection of guinea-pigs with broth which has been inoculated from the discharge. Prolonged incubation may be necessary before a positive result is obtained. Under these circumstances the patient may develop tetanus before a diagnosis is arrived at in the laboratory. Now the tetanus bacillus belongs to the same group of bacteria as do *B. aerogenes capsulatus* and *B. oedematis maligni*, and the demonstration of the presence of these two micro-organisms is a relatively simple and rapid matter. All three micro-organisms are of intestinal origin and are apt to be found in polluted soil. All three are no doubt frequently simultaneously introduced into a wound, and all three require the same conditions for growth and multiplication. The presence of either *B. aerogenes capsulatus* or *B. oedematis maligni* might with great advantage be taken as an indication for one or more

prophylactic injections of antitetanus serum. In two at least of the above cases the first symptoms of tetanus followed immediately on an operation, and it appears to us that antitetanic serum should be injected as a prophylactic measure before any considerable operative procedure is attempted on a patient with a gangrenous wound.

Since the conclusion of this investigation two other cases have been observed in which the onset of tetanic symptoms was apparently determined by operative procedure.

TREATMENT.

In the summary of our cases no reference has been made to treatment, and we did not in the first instance contemplate any reference to the matter. It may, however, be remarked that the results obtained were, considering the gravity of the majority of the cases, satisfactory; and as the bacteriological findings exhibited a marked uniformity, a brief note on the general lines of treatment may be of some interest. Cases 17 and 18 received continuous irrigation with hypertonic saline. In the other sixteen cases treatment consisted of irrigation with hydrogen peroxide (5 to 10 vols.) and fomentations of hot sterile isotonic saline solution (0.9 per cent.) or boracic lotion. In the later stages, when the wounds had cleaned up, lotio rubra and gauze dressings were employed.

After the conclusion of this investigation, irrigation with hypertonic saline solution was employed in more than 100 cases which presented similar features to those above recorded. The method caused considerable discomfort to the patients, and did not yield results in any way superior to those obtained by the use of older methods of treatment. In this connexion it may be noted that active phagocytosis was often observed in films prepared from the discharge of wounds which had been treated by the usual methods.

B. aerogenes capsulatus and *B. oedematis maligni* were frequently isolated from wounds in which no gas was produced and the gangrenous area showed no tendency to spread. It may be inferred that the conditions which enable these micro-organisms to exercise any serious influence in the course of a case are only exceptionally present. These micro-organisms are essentially saprophytes, and are relatively, if not entirely, innocuous to undamaged living tissues. The presence of dead tissue or fragments of clothing and the retention of discharge or blood clot within a wound provide these micro-organisms with a favourable culture medium. It is of the utmost importance that wounds containing anaerobic bacteria should be freely opened up and thoroughly drained.

SUMMARY.

1. The series comprises 18 cases of gangrenous wounds, of which 3 only were fatal. Included in this total are 4 cases of tetanus (1 of which was fatal), and 4 cases of gas gangrene (2 of which were fatal). Of the 18 cases *B. oedematis maligni* was found in 15 and *B. aerogenes capsulatus* in 13.
2. *B. aerogenes capsulatus* and *B. oedematis maligni* are apparently possessed of powerful enzymes. The former is peculiarly able to attack carbohydrates, the latter proteins. Dorset's egg medium is an admirable medium for both micro-organisms.
3. The shape, size, staining reactions, and capacity for spore formation of these bacilli are profoundly influenced by the nature of the culture medium.
4. On Dorset's egg medium the majority of the bacilli are typical in shape, uniform in size, and Gram-positive. On media which contain a carbohydrate, from which the bacilli can form acid, growth is at first rapid and vigorous, but after a few days the bacilli become atypical in appearance, vary greatly in size, and the majority are Gram-negative.
5. *B. aerogenes capsulatus* forms spores on Dorset's egg medium and inspissated serum, but not on media in which an acid reaction is produced. *B. oedematis maligni* forms spores less readily in acid media.
6. The presence of *B. aerogenes capsulatus* and *B. oedematis maligni* is not necessarily associated with the development of gas in the tissues.
7. *B. oedematis maligni* and *B. aerogenes capsulatus* are essentially saprophytes. They have little or no power to multiply in living tissue. In dead tissue they grow

rapidly and produce poisonous substances, by which the adjacent living tissue is destroyed and rendered a suitable medium for the further multiplication of these bacilli.

8. *B. tetani* was not found in films made from the discharge in any one of the six cases of this series in which it was present.

9. The recognition of *B. tetani* by purely microscopical methods is complicated by the fact that slender Gram-positive rods bearing an absolutely terminal spore may be occasionally found in pure cultures of *B. oedematis maligni* and *B. aerogenes capsulatus*. Moreover, pure cultures of tetanus bacilli, especially cultures on egg medium, contain many atypical forms.

10. If broth is inoculated with material from the wound in a case of tetanus, and incubated under anaërobic conditions, the presence of *B. tetani* can often be satisfactorily demonstrated by animal inoculation. Such a broth culture should be examined at intervals, and two or three weeks may elapse before *B. tetani* can be demonstrated.

11. The presence of *B. tetani* was demonstrated in the discharge from the wounds of two patients who did not develop signs of tetanus. Both had received prophylactic injections of antitetanus serum.

12. The discovery of *B. tetani* in the wounds of a patient who had not developed tetanus would obviously be an indication for one or more prophylactic injections of antitetanic serum. But the practical utility of such a procedure is limited by the difficulty and delay which attend the bacteriological recognition of this bacillus. Now, *B. tetani* belongs to the same group of anaërobic bacteria as *B. aerogenes capsulatus* and *B. oedematis maligni*. All three have probably a common source, and the conditions favourable to their growth within a wound are probably identical. The demonstration of either *B. oedematis maligni* or *B. aerogenes capsulatus* is a relatively simple matter and does not involve much delay. The discovery of either of these bacilli might with advantage be followed by a prophylactic injection of antitetanic serum.

13. A prophylactic injection of antitetanic serum should be given before any considerable operation is performed on a patient with a gangrenous wound.

THE

TREATMENT OF ACUTE TOXAEMIA SECONDARY TO GAS GANGRENE BY THE INTRAVENOUS INJECTION OF A SOLUTION OF HYPOCHLOROUS ACID.

BRITISH EXPEDITIONARY FORCE.

(Report to the Medical Research Committee.)

It has been our experience that soldiers whose wounds are infected by a gas-producing organism sometimes suffer from a condition which can only be described as an intense toxæmia and which frequently proves fatal.

Such cases present features as follows: The patient is admitted to hospital suffering from a wound of one of the extremities; there is extensive infection by a gas-producing organism, and it is obvious that the infected part must be amputated as soon as possible.

In some of these cases, although the operation is carried out, it is found that the general symptoms and signs of toxæmia do not abate but develop and deepen till death ensues; the following two cases are illustrative of these facts:

CASE A.

A sergeant-major, admitted on October 15th, 1915, suffering from a gunshot wound of the left upper arm a short distance below the shoulder-joint. There was a complicated compound fracture of the humerus, and the

brachial artery was divided. The wound was infected by a gas-producing organism, and the infection was spreading in the surrounding tissues. His general appearance was that of a man who was suffering from severe hæmorrhage; he had an intense grey pallor, and this was the more extraordinary because inquiry showed that the loss of blood had not been excessive; his features were distressed. The pulse was 130, the temperature (see Chart) 97° F., and the respirations 24. He was suffering from the condition of general toxæmia which so closely resembles shock. It was decided that amputation was necessary, but the operation was delayed for some time in the hope that matters might improve. After some hours there was no improvement and disarticulation through the shoulder-joint was carried out.

At the operation the fact was confirmed that the loss of blood was not severe, for the vessel at its site of division was twisted into a fibrous cord.

The post-operation history was disappointing, not as regards the local condition—for no trace of infection developed in the stump—but in regard to the general condition. The pallor remained, and, if anything, deepened; there was a faint underlying tinge of jaundice, there were profuse perspirations and occasional rigors, the pulse-rate increased to 150, the respirations quickened from 24 to 60, unconsciousness developed, and he died on the fourth day following the operation. After the amputation of the diseased limb there was no local site which could be regarded as the source and origin of the poisoning from which the man was suffering. A process of reasoning led to the conclusion that there was proceeding either a septicæmia or a toxæmia which had originally been instituted from the infected wound. A blood examination was carried out by Captain Ellis, but no organism could be isolated. The process was apparently, therefore, a toxæmia.

CASE A.—Gas gangrene: disarticulation through the shoulder-joint on October 15th. D, Death.

CASE B.

A private, admitted on October 30th, 1915, suffering from a gas-infected wound of the right leg. Generally he presented an appearance very similar to that of Case A—an intense pallor as though from severe loss of blood, restlessness and sweating; the temperature was 97° F., and the pulse 140. The right limb below the knee was extensively infected with a gas-producing organism; the bones were not injured, but the main blood vessels were involved. It was decided that amputation was necessary, and this was carried out through the knee-joint under spinal anaesthesia. After the operation the stump did well, but the general condition was far from satisfactory; the temperature rose and remained high; the pulse increased in rapidity and became weaker. On the morning of the second day after the operation the patient seemed better, but immediately after being dressed he collapsed and died.

CASE B.—Gas gangrene: amputation through the knee-joint on October 30th. A, Admission; O, operation; D, death.

We have chosen these cases at random from amongst others. To our minds they are illustrations of cases suffering from intense toxæmia. The removal of the original and local source of the toxæmia was not sufficient to counteract the malady, for the poison had acquired so firm a hold that its continued activity led to the death of the patients. The counteraction of the toxæmia formed a very distinct problem, and while it was under consideration Professor Lorrain Smith of Edinburgh suggested to us that eusol, which contains 0.5 per cent. hypochlorous

CASE C.—Gas gangrene; wound opened up on November 5th; amputation below the shoulder-joint on November 6th, injection of 40 c.cm. eusol at the same time. The chart shows the temperature taken every half-hour on the day on which the operation was performed and the following day. O, Operation. E, Eusol 40 c.cm. injected intravenously.

acid, might be used intravenously to combat the action of the toxin. We immediately put the suggestion into execution, and it is the result as demonstrated in three cases which we now record. Professor Lorrain Smith and those associated with him had advised us of certain experiments they had carried out proving that eusol containing 0.5 per cent. hypochlorous acid could be injected intravenously into rabbits in amounts up to 25 c.cm. without any ill effects arising.

We repeated these experiments and assured ourselves of a similar result. Thus safeguarded, we proceeded to use the solution intravenously in the treatment of toxæmia secondary to wound infection with a gas-producing organism.

CASE C.

A private was admitted on November 5th, 1915. Forty-eight hours before admission he had been struck by a bullet on the right forearm just below the elbow. The wound was dressed, but he could not be evacuated from the trenches until about twenty-four hours later.

On admission, there was found to be a gaping and ragged wound of the forearm below the elbow-joint; the bones were not broken; the main blood supply was interrupted, as no pulse could be felt in either radial or ulnar vessels. The wound was sloughing, and apparently infected by a gas-producing organism. The general condition was bad; he had an unhealthy toxic appearance, and was somewhat blanched. The temperature was 100° F., and the pulse 120.

As there was some evidence of a collateral circulation being established, attempts were made to conserve the limb. Under anaesthesia the wound was thoroughly opened up; various fascial planes were exposed, and the parts were freely dressed with eusol.

On the morning of November 6th the patient was distinctly worse; sleep had been broken and imperfect. His general appearance was decidedly grave; he was blanched as though from a severe haemorrhage, with a yellowish discoloration of the skin. He was slightly delirious. The pulse-rate was 150, and the temperature had fallen to sub-normal, 98° F. The local condition was correspondingly worse; there was complete arrest of circulation in that portion of the arm distal to the wound. There was emphysema from the centre of the upper arm to the neighbourhood of the wrist; there were patches of a bluish discoloration of the skin, and the muscles in certain parts showed distinct necrosis.

At 3 p.m. the arm was removed just below the shoulder-joint, and immediately after the operation 40 c.cm. of eusol were injected intravenously. From this time the temperature rose almost continuously for three hours, and at 7 p.m. it had reached 102° F.; the pulse-rate likewise correspondingly increased from 120 to 160. Immediately after operation it fell from 150 to 120 and then rose again. From 7 p.m. until midnight the temperature remained at about 102° to 101° F., and the pulse remained about 160 (see Chart). Soon after midnight the temperature began to fall until at 8 a.m. on November 7th it had reached 99° F.; the pulse likewise fell from 160 to 108.

During November 8th, 9th, and 10th there were successive rises of temperature, usually occurring in the early morning and accompanied by corresponding increases in pulse rate. On November 15th the temperature fell to normal and remained so.

There were other changes to be noted in addition to those in pulse and temperature. The general appearance improved by leaps and bounds; the ashy pallor disappeared within twenty-four hours, to be replaced by a slightly flushed appearance. The respirations altered strikingly; previous to operation and injection of eusol the respirations were deep and slightly stertorous, such as gave us the impression of a sense of air hunger. Subsequent to operation and injection they became quicker, shallower and less noisy. Shortly after operation and injection the restlessness disappeared and the patient slept comfortably.

The further progress was one to complete recovery.

Immediately before the injection of eusol was given blood was taken for bacteriological examination; both aerobic and anaerobic cultures were negative.

CASE D.

A private, admitted on November 16th, 1915. About twelve hours before admission he had sustained a bullet wound through the left arm about the level of the elbow joint. There was considerable bleeding and a tourniquet was applied. Beyond a simple dressing nothing further was done, and the patient was sent into hospital with the tourniquet still in position.

On admission it was found that the brachial artery was severed immediately above its division; the vessel was tied. There was no definite evidence of infection in the wound, but it was thoroughly opened up and treated with eusol. There were signs that an adequate collateral circulation might be established.

CASE D.—Gas gangrene; wound opened up on the morning of November 17th, amputation same evening. Injection of eusol 40 c.cm. at 3.15 p.m. on November 18th. A, Anaesthetic; wound opened up, etc. M, Morphine, gr. ½. O, Operation. D, Digitalin, gr. rds. S, Saline, 3 pints. E, Eusol, 40 c.cm., intravenously at 4 p.m.

On the morning of November 17th the general condition of the patient was unsatisfactory; he had had a restless night, and there was some evidence of gas in the neighbourhood of the wound. The wound and fascial planes around were further opened up. He was pallid and slightly jaundiced, restless, and sweating slightly.

At 10 p.m., on dressing the wound, it was found that the condition had become much more extensive. There was gas throughout the forearm and extending upwards along the vessels as far as the axilla. It was obvious that operation was necessary, and at 11.30 p.m., the arm was amputated below the shoulder-joint and partly through the infected area. After the operation there was evidence of collapse; the temperature fell to 98° F., the pulse was 126.

Stimulation was carried out with saline, 3 pints subcutaneously, and digitalin $\frac{1}{10}$ grain.

During the morning of the 18th the condition became more serious; the temperature continued to fall, and reached 97° F.; the pulse increased to 126-124; the respirations were full and stertorous, resembling a condition of air hunger. The general appearance was one of pallor with a tinge of jaundice. At 2 p.m. the condition had become so serious that it was obvious that something further ought to be tried, therefore at 3.15 p.m. 40 c.cm. of eusol were injected intravenously with a Record syringe. Before injection a blood examination was made, but no organism was isolated.

At 4 p.m. the temperature was 98.6° F. and the pulse 136; there was no obvious change in general condition. At 4.30 p.m. the temperature was 100° F. and the pulse 136; at 5 p.m. the temperature was 101° F. and the pulse 136; and at 7 p.m. 102.5° F. and 140 respectively. By this time also there was a change in the general condition; he was sleeping peacefully; respiration was quicker and quite quiet; his colour had improved, and the pallor was replaced by a slight flush.

By midnight the temperature had begun to fall and was 100° F.; the pulse was 120.

On November 19th his condition was greatly improved; the temperature was 99° F., the pulse 100; he was sleeping well and taking nourishment, and the local part looked well.

The further progress was one of uninterrupted recovery.

Some of the facts in regard to this case call for special attention. The operation of removal of the arm did not produce any benefit; in fact, after it the general condition grew steadily worse. The collapse was so intense that it was thought to be the result of loss of blood; but the reaction after the intravenous administration of eusol was so correspondingly great that we had no hesitation in saying that the alarming symptoms were the result of an intense toxæmia. The eusol was not given until sixteen hours had elapsed from the time of operation; and before the drug was given we were agreed that the prognosis was absolutely hopeless.

CASE E.

A private was wounded in the calf of the right leg by a shrapnel bullet on the afternoon of December 6th, 1915. He was admitted to hospital on December 7th about midday. The neighbourhood of the wound was found to be infected by a gas-producing organism. The general condition was bad; there was pallor as though from loss of blood; the temperature was 100° F., and the pulse 120. Arrange-

CASE E.—Gas gangrene; amputation through the knee-joint on the afternoon of December 7th. Injection of 70 c.cm. eusol. The chart shows the variation of temperature at each half hour during the first six hours after the operation. O, Operation, 70 c.cm. eusol intravenously.

ments were made to have the wound opened up, but pressure of work rendered it impossible to have this done until 2.30 p.m. (two and a half hours after admission). At this, the second, examination it was found that the condition had become much graver: the leg below the knee was enormously swollen; it was as resonant as a drum from knee to toes, and signs of infection had extended along the line of the femoral vessels as far as the centre of the thigh; there was an entire arrest of circulation in the foot and leg. The general condition was correspondingly worse; the temperature had reached 102.5° F., and the pulse-rate was 130.

Half an hour later, when the patient was in the operating theatre, a further advance had been made which

we could hardly have believed possible in so brief a space of time. In places the skin of the leg was becoming mottled as the result of actual tissue necrosis; the gas infection of the thigh had extended upwards as far as the groin. The general condition had become correspondingly worse. Disarticulation through the knee-joint was performed by the Stephen Smith method; it was necessary to cut through infected tissue, but former experience had told us that this could be done. The cutting of the flaps revealed green, foul-smelling subcutaneous tissue; free incisions were made along the whole length of the femoral artery as far as the groin; the knee-flaps were left open and drainage of the thigh wounds was thoroughly secured. Before the patient left the theatre 70 c.cm. of eusol were injected intravenously; the dose was larger than usual because from our former knowledge of such cases we took an exceedingly grave view of this case.

His history after operation exceeded even our most sanguine expectations; there was no further appearance of gas formation or gangrene, and forty-eight hours after operation his pulse-rate had fallen to 88. His condition in the future never gave us the slightest cause for anxiety. Under usual circumstances we should have regarded this case as very likely to prove fatal, or at least to have recovered only after a prolonged period of debility.

Blood Cultures.—These were made for both aerobic and anaerobic organisms. For the aerobic ordinary plates of 1 per cent. glucose agar were employed, and 1 c.cm. of blood was introduced. Three kinds of anaerobic cultures were made use of in each instance: (1) Plates as above, but grown in a carbon monoxide atmosphere; (2) 1.0 c.cm. of blood in litmus milk in a Buchner tube; (3) 1.0 to 2.0 c.cm. of blood in an ordinary shake culture in deep 1 per cent. glucose agar tubes.

COMMENTARY.

There is really very little which we wish to add of the nature of a commentary. The position, briefly, is as follows: We were faced by the fact that men suffering from an infection of their wounds by a gas-producing organism frequently succumbed to what to our minds appeared to be an intense and progressive toxæmia. The first two cases (A and B) which we have described are illustrative of such a condition.

We found extreme difficulty in antagonizing and treating these toxæmias. Following Professor Lorrain Smith's suggestion, we are now using intravenous injection of a solution containing 0.5 per cent. hypochlorous acid (eusol) for this purpose, and, to our minds, the results which we have obtained most thoroughly justify the adoption of the method. We have quoted three cases illustrative of the treatment (Cases C, D, and E). Before the injection of the hypochlorous acid solution these were, in our opinion, as dangerously ill as the two illustrative cases (A and B) which we have described, and we believe that the eventual recovery which the three (C, D, and E) made was due to the action of the hypochlorous acid.

A striking feature of Cases C and D is that at the time of the operation the patients were in a condition of collapse, as was evidenced by the progressive fall in temperature and the general state. In Case D the collapse continued for fourteen hours after the operation. The disappearance of the signs of collapse took place after the intravenous injection of eusol. In both cases (C and D) the injection was followed by an immediate rise of temperature. This is to be looked upon as a sign of reaction, for even during the pyrexia a clinical improvement became evident, and the fever was a precursor of steady recovery.

Case E indicates that it may sometimes be advantageous to give a larger dose. In a note on the successful treatment of a case of puerperal septicæmia by intravenous injection of eusol, published by Lorrain Smith, Ritchie and Rettie, it is stated that an injection of 100 c.cm. eusol was given, and this was repeated after twenty-four hours without any indication of untoward effect on the patient.

The solution employed for injection was eusol containing 0.5 per cent. hypochlorous acid, to which was added 8.5 grams of sodium chloride per litre. The solution was carefully standardized before injection. The injection was made by means of a Record syringe into the median basilic vein. In two instances 40 c.cm. of hypochlorous acid (eusol) were injected; we were prepared to repeat the injection, but the recovery was so progressive that

repetition was not necessary. In the third case 70 c.cm. of eusol were injected.

We wish to acknowledge our indebtedness to Lieut.-Colonel West, R.A.M.C.(T.), for permission to study these cases; also to the staff of the Canadian Mobile Laboratory, who carried out the necessary bacteriological work.

NOTES ON CLOTHING AGAINST COLD.

BY

W. T. GRENFELL, C.M.G., M.D. OXON.,

SUPERINTENDENT OF LABRADOR MEDICAL MISSION, ROYAL NATIONAL MISSION TO DEEP SEA FISHERMEN.

THE following brief notes are founded upon experience gained in Labrador and North Newfoundland during the last five-and-twenty years; they express not only my own opinion, but the winter practice of those who live and work in the countries mentioned.

The source of heat being the body, and the chilling of the body being the result of loss of heat, we design our garments against this issue, and I may say at once that we do not use india-rubber boots or any waterproofed garments.

Exercise being conducive to increased production of heat, we make our clothing very light and see that the material is as far as possible (1) thin and pliant, (2) wind and waterproof, (3) durable, (4) inexpensive.

We always use two layers of light material instead of one-layer of heavy. We never use flannel or wool outside, but as it contains air spaces and can be woven thick, soft, and light, we use a thick undergarment and a very light outside one. The colder it is the thinner material we use for boots, because it is more pliable.

Jumper.

The general plan of the upper garment is always the same. To adapt it for use in Europe in mild climates where rain is frequent we should use light Willesden canvas outside, or Burberry or light waterproof rubber material. When very cold we wear a second loose one underneath. The essential point is that there shall be no draughts.

1. At the neck draughts are avoided by making the capot, or hood, continuous with the body piece.

2. Leakage in front is avoided by making the jacket in one piece and getting into it from below.

3. Leakage below is avoided by a canvas or webbing belt fastened on to the lower edge of the jacket, or heavy elastic sewed in, or a soft pliable thong running through a gusset.

4. Leakage through the arm is avoided by a rubber band round a reversed cuff inside (as shown in Fig. 1), or

FIG. 1.—Showing the jacket (jumper) and the hood (capot); also the harness for carrying gloves. The waist band and the left wrist band are open.

webbing strap sewn on the outside edge of the sleeve cuff, exactly as the belt is attached.

5. Leakage round the face is stopped by a draw string round the opening.

The best belt fastenings are without any buckle, but have glove push-fastenings and a thong going through an eye. They can be opened and closed in a moment with gloves on.

In hot weather the sleeves and belt can be loosened and the hood thrown back, so that the wearer has a cool light garment. It is a funnel through which air blows. There is no garment on earth to beat it; it cramps nothing, no snow can get inside, nor can rain, especially when two are worn. It is the next thing to a diver's suit when in use, and makes a splendid bag or sack when not in use. With No. 2 canvas it can be used as a wash-basin if wanted. The breath can also be kept in more or less to add to warmth at a pinch, if the capot is loose enough. We often carry light articles in our capots as we run along by the sledges. When in extreme cold we use two; one is often of mere calico over one of duffel or blanket. The canvas is easily cleaned from mud when dry. There are no folds to catch on obstructions.

Gloves and Mitts.

Our mitts, when we are shooting, have the right index separate. All our gloves are double, the outside being skin, or wind-proof material, light and soft, and water-tight if possible. The inside mitt is woollen and soft and thick. The glove always goes over the sleeve, and has a strap as well round the wrist (Fig. 2). The inside glove

FIG. 2.—t, Travelling glove or mitt. s, Shooting gloves. The strap at the wrist is of canvas or rubber; the upper strap is of canvas.

alone might have a separate index finger. Lastly, we suspend the outside mitts by a string round our necks, so that we can leave them dangling when we throw them off in a hurry.

Trousers.

For trousers we use the same material as for the jumper, canvas or "duck" (Fig. 3). We find the chest

FIG. 3.—Side and front view of trousers. The braces are sewn on to the trousers at the back. They are usually made of canvas, but might be of elastic. When desired the knee strap can be loosened and the trousers worn as running shorts outside the boots.

flap coming right up from the breeches a very great saving of heat. The back should also be above the waist; there can then be no leak of heat. The trouser always goes well inside the boot tops. We use no opening for urination—the trouser is all in one piece. A flap might be made if necessary, but we want no draughts.

Boots and Socks.

For boots we use sealskin and deerskin. Deerskin boots are the warmest, but are not watertight; we use them in hard frost.

Our boot materials are, as are all our garments, soft, light, and water and wind tight (Fig. 4). There are no nails and no pegs. The sole is soft; we use no thread; all are sewn with tissue from tendons, and as these swell with wet they never leak. We soak the boot or rub it over with tar and oil. It wants careful treatment to keep it from tinting or rotting, as we use raw or green skins. These are the most watertight. The hair is shaved off, and so there are no holes left in the leather. Occasionally we tan these skins and then soak them in tar and oil. It would be hard to get any number of these boots from Labrador now, as the

FIG. 4.—Boot.

coast is shut off from communication. They could not be obtained in any quantity till autumn, though a few thousand pairs of the tanned boots might be obtained in a few months, especially if the old sealskins from the Newfoundland fishery were purchased for the purpose. I think, however, skins of pigs or goats or dogs, and possibly sheep, would serve just as well. The features are, first, that they should be absolutely soft and very thin, so that the foot can move in every joint and keep warm. They are large and loose, and strap or tie round the knee. Very often, especially in spring, we carry the boot above the knee and tie it again, as then we can kneel to shoot or crawl on wet ground. The boot will take easily three pairs of socks. Very often in wet weather we use a pair of shoes of the same material, or of tanned skin inside the boot, and then two pairs of socks. These will keep dry on wet ground all day. The outer thin boot when of tanned skin "seeps water" a little, and the inside shoe keeps that from the sock. The looseness of the boot would prevent anything like "trench foot" from pressure. The boots are perfectly good on stony ground, the number of socks inside prevent the stones cutting the boot, and very soon the wearer does not notice the inequalities. We use them often, long after all the snow is gone, on our rocky hills and shores.

The sewing is always done with sinews. The fascia lumborum of the deer is dried and thread made from it by tearing the fibres and twisting them. This swells with the wet and prevents any leaking. Also the sewing is done exactly like sewing bowel; the stitches go only half way through the skin.

To demonstrate the way they resist water I would say our kajaks, one of which I always use for shooting on the sea, are only of one single layer of this sealskin, sewn together with this same sinew in this way, and they never leak a drop. I have driven my kajak through rough water, hunting all day, and never got damp even. One can run and jump in this costume as one did in football flannels. Among our doctors we have had more than one 'varsity runner and other athletes, and it is the unanimous opinion that when we get rid of our hard boots at the beginning of the winter, and abandon our conventional European clothing we begin to know what ease and comfort in moving is, and what resisting cold and wet means. There is no hard boot made that will save a foot from frost-bite. The sealers travelling over the sea ice put a thin tap or sole, pegged into our thin sealskin boot, so that they can screw in the "chisel" and "sparble" that prevents slipping.

This soft boot also allows yet another very important improvement over any hard boot. There is so much room in the boot that if the feet are cold and wet socks can be discarded and grass or hay used instead. The hay is just twisted into a hank loosely and bound round the foot, enough to enable one to distribute it around in the boot. A wisp is first put into the toe and on the sole. Hay is cheap—grass is easy to get. The air spaces are very warm. It takes a lot of water to wet hay. The foot sweats less in hay than in wool. There is no reason,

however, why one sock should not be worn inside the hay. When hay is wet, it can be changed by putting it into the cap or capot to dry from the heat of the body, as a scout does his matches. The "Lap" always uses grass in his skin boots, and wears the change grass in his tam-o'-shanter or knitted cap. The soft wading stockings are rendered almost useless in a hard boot—as the boot must be large and clumsy. They could readily be used in a perfectly soft boot.

A vamp is a low shoe made in wool (Fig. 5). The shops sell them. But much the best are those we make by

FIG. 5.—A, Vamp in knitted wool. B, Cross sections of vamp with wisps of raw wool drawn in. C, Vamps one over the other.

knitting the vamp, and then drawing in wisps of raw wool through the meshes, so that all the raw wool is inside. This gets trodden into a thick soft layer. The wool can be left greasy if preferred. It is very warm, and not easily wetted. To show how soft a boot is I would add that when one is wet and it has been taken off we turn it inside out and hang it up to dry. If a raw skin boot is hard, when we are putting it on we rub it on a boot stick and break it soft again, or just throw it in a bucket of water. The boots are so light that a spare pair could easily be carried to the trench and used as a pair of water-proof bags for rations if necessary. We never use any overcoat, hard hat, or hard belt, or any clumsy, heavy, hard contrivance at all.

Lice and fleas cannot breed in canvas and linen, as they can in hairy sheepskins and goat, and the heat necessary can yet be retained.

CHLORAMINE IN THE TREATMENT OF WOUNDS OF THE MOUTH AND JAWS.

By STAFF SURGEON A. R. FISHER, R.N.,

H. M. HOSPITAL SHIP "REWA."

(Report to the Medical Research Committee.)

THE septic character of all gunshot wounds involving the mouth and the disadvantages attending the use of the common antiseptics led me to try in these cases a new agent—chloramine (toluene sodium sulphochloramido).

The suggestion was made to me by Dr. H. D. Dakin, by whom the preparation was made. He advised a 2 per cent. aqueous solution for use as an irrigant and mouth wash.

During the months of October, November, and December, there was a great falling off in the number of surgical cases received on board this ship, but I was able to try the effect of this agent in seven cases, and in all the result was highly satisfactory. Where necessary, the usual surgical procedures were carried out under an anaesthetic, such as the opening up of external wounds, the removal of loose bone, teeth, foreign bodies, and ragged portions of tissue, the arrest of haemorrhage, and the suturing where possible of severed tissues—for example, the soft palate. Tubes were inserted through the wounds and the mouth to allow access of the injected fluid to all the damaged surfaces. The external wounds were dressed in the usual way, but the distal ends of the tubes were allowed to project outside the bandage, so that the reagent could be introduced frequently without disturbing the dressing. Irrigation was carried out every hour during the day, and as often as possible during the night, the patient sitting up in bed. Three or four syringes (2 oz. capacity) were injected through each tube, the fluid returning through the mouth into a receptacle. The patient was fed through a tube, irrigation with the chloramine solution being carried out immediately before and after.

Chloramine, besides being a powerful antiseptic, has the property of penetrating the tissues, and is not so readily neutralized by albuminous discharges as the simpler chemical antiseptics; also it is bland and quite pleasant to use, being non-irritant.

Of the 7 cases treated with chloramine, 5 were compound fractures of the jaw and 2 were flesh wounds involving the mouth. The following are clinical notes of these cases:

CASE I.

P. C., wounded at Anzac on October 6th, was operated on nine hours later under an anaesthetic for a rifle-bullet wound of the upper jaw. The bullet had entered the right cheek just below and in front of the malar prominence, shattering the right supramaxilla, plunging up the soft palate, removing some teeth of the left upper jaw, and then passing through the left cheek, leaving a large ragged wound. The wounds and surrounding skin were cleansed with hypochlorite solution, the ragged edges cut away, and many small fragments of bone removed. A tube was inserted through the exit wound into the palate region and another through the mouth; the latter was kept in position by a safety-pin through the bandage. The mouth was irrigated every two hours with chloramine and the wounds dressed twice daily. He was fed every four hours through the tube.

Six days later he was able to gargle for himself and drink fluids. On October 18th he was discharged to H.M.H.S. *Aquitania*. The wounds had remained clean, and there had at no time been any purulent discharge or offensive smell from the mouth. I am informed that ten days later he was landed in England with the wounds almost healed and the mouth condition satisfactory.

CASE II.

F. L. sustained a shrapnel wound of the right upper jaw on October 13th at Helles. He was received on board twenty-four hours later suffering from marked dyspnoea. Under chloroform he was found to have a compound fracture of the right upper jaw and laceration of the palate. The wounds were cleansed, and a shrapnel bullet and a tooth were removed from the posterior pharyngeal wall. No tubes were inserted. The patient was able to gargle frequently with chloramine and to drink fluid.

On October 18th he was discharged to H.M.H.S. *Aquitania*. During this period the breath remained inoffensive and the tongue clean.

CASE III.

W. G. T. was wounded at Anzac by shrapnel on October 27th. Two days later he was received on board, and examined under an anaesthetic. He was found to have extensive flesh wounds of the right arm, and a compound fracture of the right lower jaw; all wounds were very septic and the breath fetid. The wounds were irrigated and dressed with hypochlorite, and a chloramine mouth wash ordered to be used every two hours.

On November 2nd, when the patient was discharged to hospital at Malta, the external jaw wound had cleaned up considerably, all surrounding inflammation had subsided, and only a slight purulent discharge remained; the mouth had become quite clean, and the breath inoffensive.

CASE IV.

T. G. was wounded at Suvla on November 8th. An operation was performed sixteen hours later for a penetrating rifle bullet wound; the entrance was at the right mastoid process, and the exit through left cheek; it had injured the base of the skull, the hard palate, and the left supramaxilla. The right ear was cleansed with hypochlorite and plugged with gauze. The wound of entrance, through which cerebro-spinal fluid was leaking, was cleansed and dressed, and a tube inserted through the exit wound into the palate. Daily dressing and hourly irrigation with chloramine was used.

On November 13th he was discharged to hospital at Alexandria, the wounds clean, and the mouth being inoffensive.

CASE V.

W. T. received on December 7th, near Salonika, a rifle bullet wound at the angle of the left lower jaw, causing compound fracture of jaw. There was no exit wound.

He was received on board this ship on December 14th; the wounds were very septic, the mouth foul, and the breath exceedingly offensive. There was much submaxillary swelling and adenitis. The external wound was treated with frequent hypochlorite dressings and the mouth with chloramine wash. The condition rapidly improved, the oral discharge decreased, and the submaxillary swelling subsided. On December 20th a bullet was detected lying on the right side deep to the floor of the mouth. It was extracted through a skin incision. The patient is now making a good recovery.

CASES VI AND VII.

The other two cases were both recent flesh wounds involving the buccal cavity, but not injuring bone. They both remained clean and healed in a few days.

The number of cases treated is small, but the results were so encouraging that a short account of this method may be of value. No such rapid and satisfactory results have followed the application of the antiseptics commonly in use.

COMBINED PREVENTIVE INOCULATION AGAINST TYPHOID AND PARATYPHOID FEVER AND BACILLARY DYSENTERY.

BY

J. PRATT JOHNSON, M.B.LOND., D.P.H. OXON.,

AND

A. J. MILNE, M.B., D.P.H.,

ASSISTANT MEDICAL OFFICER OF HEALTH, JOHANNESBURG.

(Preliminary Note.)

It has been shown by Widal, Sicard, Castellani, and others that the employment of mixed bacterial vaccines has a sound experimental and clinical basis, and marked success has followed the use of a mixed typhoid + paratyphoid A + paratyphoid B vaccine for preventive inoculation both in Europe and German South-West Africa.

We have made investigations into the possibility of amplifying the scope of preventive inoculation so as to afford protection not only against typhoid and the paratyphoid infections but also against bacillary dysentery. The intense toxicity of *B. dysenteriae*, especially in the Shiga strains, constitutes a serious difficulty in regard to the use of dysentery vaccine. In a short note published in the *BRITISH MEDICAL JOURNAL* of August 8th, 1914, Broughton-Alcock points out that this may be largely overcome by submitting the bacteria to a treatment with normal heated serum, and by employing this technique he was able to use doses of 350 and 700 million dysentery organisms in some 200 cases, producing reactions which were never marked nor inconveniencing. The reduction in the amount of local reaction is due to a non-specific action of the serum on the bacilli. Our method depends upon the use of a dysentery vaccine completely sensitized with a heated polyvalent dysentery serum. The vaccine is prepared from Shiga, Flexner, Kruse, Hiss, and Russell strains in equal proportions. In all some 150 inoculations were carried out among individuals kept under close observation for some fourteen days; 60 per cent. of these were actually engaged in heavy manual labour, which they carried on during the period of observation.

For the purposes of comparative observations and controls a small series of inoculations were carried out among hospital patients, who volunteered, with varying doses of untreated dysentery vaccine, both alone and mixed with typhoid + paratyphoid vaccine.

CONCLUSIONS.

1. Inoculations with untreated dysentery vaccine, either alone or combined with a typhoid + paratyphoid vaccine is not under any circumstances justified, owing to the severity and duration of the local reaction.

2. Complete sensitization of dysentery vaccine produces marked reduction in local reaction, and general reaction is very exceptional.

3. The use of a typhoid + paratyphoid vaccine, combined with sensitized dysentery vaccine, is a practical proposition from a military point of view, and can be employed in doses sufficiently large to produce a satisfactory immunity, while the local reaction is practically in all cases slight. Such a vaccine should contain in 1 c.cm. *B. typhosus*, *B. paratyphosus* A, and *B. paratyphosus* B 500 million in a ratio of 2, 1, 1 plus *B. dysenteriae* (sensitized) 250 million. A dose of 1 c.cm. is recommended as a first inoculation, followed by a second inoculation of the same amount after an interval of seven or eight days. A third inoculation may be made, but is not essential. It is important that the inoculations should be made in subcutaneous tissue over muscle. In our experience the pectoral region is convenient. In order to ensure accurate doses, a 1 c.cm. syringe with a moderately fine needle should be used.

4. *Agglutination Reactions.*—After one inoculation of a combined untreated vaccine specific agglutinins are found in the blood after an interval of nine to fourteen days for each of the four organisms present. Immunity is therefore rapidly produced, and it would appear that complete sensitization of the dysentery organisms not only reduces the local reaction, but produces a much more rapid and satisfactory immunization, owing to the more complete disintegration of the treated organisms and the absence of any mechanical obstruction (such as localized fibrosis) to the blood supply of the affected area.

5. We anticipate that even a further reduction in local reaction will be obtained on the employment of a mixed vaccine prepared from typhoid, paratyphoid A, paratyphoid B, and dysentery organisms, completely sensitized with their respective antisera.

We propose shortly to publish full details of our observations in regard to the use of this vaccine.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

STRANGE WOUNDS CAUSED BY HIGH EXPLOSIVES.

ABOUT twenty years ago three men were concerned in a nitroglycerine explosion, and two of them lost their lives and one—less hurt—his reason.

They were sitting by the fireside in a small cabin, "having a smoke" after breakfast. One of the number was also busy trying to readjust the composition of some dynamite which he had been tempering on the hob in an old salmon tin. Becoming heated too much, the nitroglycerine separated from the earthy matter and formed a jelly-like lining on the inside of the tin, and this the unfortunate man—who described his action fully and confidentially to the writer just before he died—was endeavouring to scrape off with his pocket knife.

A terrible explosion occurred, and two of the men presented extraordinary wounds, especially on the thighs, and in only one wound (a chest one) was any trace of metal found. In the thighs and trunk the chief feature was a small external wound leading into a large cavity churned up and softened. One unfortunate man had both eyes quite burst up, as if a rough attempt had been made to gouge them out.

The oldest man, who, it seems, was furthest away and thus less injured, was quite mentally upset, and not able, when he recovered consciousness, to give any particulars of the accident. His mind was such a blank that it was thought that he was malingering, in order, being a fireman, to escape responsibility.

At the time I came to the conclusion that the strange wounds were caused by the escape of internal body pressure into the vacuum produced by the explosion, the particular situation being determined by certain spots in the integument being accidentally punctured and a funnel-shaped cavity produced. There was very little damage to clothing and practically no burning.

Newport, Mon.

J. LEWIS THOMAS, M.D.

THE VALUE OF ANTITETANIC SERUM.

CAPTAIN KILNER'S paper in the JOURNAL of January 8th on a severe case of tetanus successfully treated by antitoxin is very interesting, and I have no doubt that at the end of the war there will be a full report of cases of tetanus treated by serums, as also cases of lacerated wounds in which prophylactic doses of serum have been given.

In the BRITISH MEDICAL JOURNAL for December 24th, 1910, I published two cases of acute tetanus in which antitoxic serum was used and the patients recovered. In cases of lacerated wounds prophylactic doses were recommended to be given as soon as possible.

Since 1910 other two cases have come under observation and recovered with the serum treatment. The serum was injected into the soft part of the hip every twelve hours until the symptoms improved and then every twenty-four hours until recovery was complete.

Both in hospital and private practice prophylactic doses of serum have been used with the best effect. Even in comparatively slight lacerated wounds where contamination with earth or dirt of any kind was possible, in addition to thorough cleansing, the prophylactic dose of serum was invariably given.

Microscopic examination of discharges from wounds is essential, but no delay must take place in giving the serum, as it is important to anticipate the absorption of the bacillus. In the cases of acute tetanus which came under my care Professor Muir found the bacillus; on the

other hand, its absence does not justify withholding the serum if the symptoms and local conditions indicate that it is necessary.

J. CRAWFORD RENTON, M.D. Edin.,
Lieut.-Col. R.A.M.C.(T.).
Edinburgh.

TWO CASES OF STONE IN THE PROSTATE.

CASE I.—A. B., aged 78, came to me in June, 1913, complaining of stricture. With difficulty I got the smallest filiform catheter into the bladder. On rectal examination a very hard, fixed, but even mass was felt at the site of the prostate. The condition was, therefore, calculus or malignant disease. To decide the point quickly I passed a needle through the perineum; it struck a calculus. In company with Drs. Browne and Scott I opened the bladder suprapubically, and removed many stones (earthy phosphates) from a cavity which now was the only relic of the prostate left. I then cut the stricture. He made an excellent recovery.

CASE II.—In April, 1914, I operated on C. D., aged 76, assisted by Dr. Duncan of Richmond. The history was that on two other occasions stones had been removed suprapubically. Years ago I removed both testes for disorganizing suppuration. We removed the stones through the perineum, having slowly dilated the membranous urethra by the finger. The whole bladder, and especially its neck, where some of the stones lay, was encrusted with phosphates impossible to remove save by a curette. I therefore curetted them off, paying special attention to the cavity in the prostate. He made a good recovery.

There were some points of interest and importance in these cases.

1. A. B. had a severe rigor, and collapsed before he gained consciousness, and had rigors (and subsequent fever) each time, and immediately I douched his urethra, and more markedly when this canal was distended, even in its anterior part. He had therefore reflex urethral fever, in contradistinction to infective urethral fever (terms which should be used).

2. The simple and inexpensive means of making a diagnosis between calculus and malignant disease.

3. C. D. suffered for some years after the orchidectomy, just as a woman suffers after the menopause, and at his age (76) this is interesting. He had frequent flushings and sweatings, strange feelings in his head, irritability, etc. These were partially relieved by orchitic extract.

4. C. D. was also left with some degree of urinary incontinence. This might, I think, have been avoided had I adopted, as I did in other cases, gradual instrumental dilatation of the wound before the introduction of the finger. This applies also to perineal prostatectomy, provided the organ is removed through the wound in pieces.

London, E.C.

JAMES MACMUNN.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

FULHAM MILITARY HOSPITAL.

THE medical staff of this hospital has instituted fortnightly meetings for the discussion of cases. At the third meeting, on December 21st, 1915, Major PARSONS, O.C., being in the chair, Lieutenant CUMMINGS showed a case of aneurysm of the arch of the aorta, due apparently to violent concussion by an exploding shell, the symptoms developing immediately afterwards, and there being no history of syphilis. He also showed a case of auricular flutter supervening on the stress of military service, but giving a suggestive history of several attacks of sudden unconsciousness previous to enlistment; and a case of pericarditis and aortic valvular disease, with enormous enlargement of the heart, in which great improvement had followed the use of thyroid gland medication. The signs of hypothyroidism were very slight, but of the usual character.

Mr. CHAPPLE showed two cases of spiral fracture in the

lower third of the tibia, with marked eversion of the foot after union; in one, subsequent replacement of the bone and plating had resulted in a good position and a useful foot. He advocated operation in every case possible, but in septic compound fractures it was necessary to wait for long after the wound was completely healed before attempting any surgical interference.

Dr. GAY showed a patient giving a history of attacks of vertigo, vomiting, and abdominal pain, extending over four years; since admission he had developed nystagmus and a tendency to fall backwards. The vertigo was of the intracerebellar type—that is, he had a sense of rotation, external objects appearing to move in the same direction. The abdominal reflexes were diminished. Dr. Nourse, otologist to the hospital, had pronounced against labyrinthine disease. In a very illuminating review of the case Dr. KINNIER WILSON, neurologist to the hospital, gave grounds for the belief that no one lesion would explain both the nystagmus and the diminution in the abdominal reflexes, and stated his opinion that the case was probably one of early insular sclerosis.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

STAFFORDSHIRE BRANCH.

THE first general meeting of the session was held at Stoke-on-Trent on November 18th, 1915, when the President, Dr. F. M. ROWLAND, was in the chair. Dr. MITCHELL SMITH read a paper on *Alimentary hygiene in children* in which he pointed out that the two chief causes of infantile mortality were (1) insufficient care of the mother in the prenatal life of the child, (2) artificial feeding. He briefly described pyloric spasm and stenosis, the routine treatment of epidemic diarrhoea at the Evelina Clinic, advocated examination under an anaesthetic in suspected cases of abdominal tuberculosis in children, and drastic restriction of milk fluids and carbohydrates in the treatment of these early cases. After referring to the frequency with which stomach cough is mistaken for pulmonary tuberculosis in children, he concluded by emphasizing the importance of schemes for children's welfare at the present time and stated that the country was under a debt of gratitude to those who were inaugurating classes and demonstrations to teach the young mother her duty towards her offspring.

In a paper on *Nose bleeding*, Mr. G. A. CARTER urged the necessity of conducting all examinations of the nose with the aid of proper illumination and a speculum, and showed a small portable dry-cell battery and head-light which he found of great use. The post-nasal use of plugs was condemned as obsolete, and the dangers attending the use of any kind of packing in the nose were discussed. The value of hydrogen peroxide as a haemostatic in nasal cases was urged, and all styptic drugs, such as perchloride of iron, condemned as dangerous.

MESSRS. S. McMURRAY and E. E. YOUNG presented a paper on a *Case of intracranial new growth simulating miner's nystagmus*.

J. D., aged 36. Previous history unimportant. In February, 1911, a stone struck his left eye, causing a traumatic cataract. After treatment he worked for six months as a timberer, but had to stop on account of pain in his injured eye. When examined in February, 1915, he was suffering from miner's nystagmus, rotatory in type. Right vision (with glasses) = $\frac{3}{4}$; fundus normal. Left eye, aphakia—divergent strabismus; fundus normal. Examined again in June, 1915. He had not worked down the pit since February, 1913. Complained of severe frontal headaches; blurred vision. Right vision = $\frac{3}{4}$; faint jerky irregular nystagmus on looking up; fundus normal.

On August 20th, 1915, he complained of severe frontal headaches for past six days; no sickness, giddy. Right vision = $\frac{3}{8}$. Right disc was swollen 2 D., field contracted. Wassermann reaction positive.

August 26th, 1915. Decompression.

September 16th, 1915. Right vision = $\frac{3}{4}$; fundus normal.

The authors considered the case interesting in that the symptoms of miner's nystagmus apparently returned, and that until papilloedema developed there was no reason to suspect intracranial new growth.

Rebuelus.

FIBROSITIS.

THE authors of this encyclopaedic work on *Fibrositis*,¹ or inflammation of some portion of the white fibrous tissue of the body, are to be congratulated upon the thoroughness with which they have executed their task. Their task has been to extract and characterize one class of cases from the clinical *omnium gatherum* known as "chronic rheumatism." As everybody knows, "rheumatism" is a term that has been so widely and so loosely used as to have lost all definite meaning—except, indeed, to the actual sufferer. Clinically, the word "rheumatism" has been more abused and misapplied in the description of all chronic painful affections than even "influenza" has in the diagnosis of acute infections of unknown etiology. Drs. LLEWELLYN and JONES argue that the term "chronic rheumatism" contains three entities at the present time, namely: (1) Chronic articular rheumatism, (2) muscular rheumatism, and (3) neuralgic rheumatism, each containing subvarieties that may be classed as infective, toxic, traumatic, static, and so forth. They propose to restrict the name "chronic rheumatism" to the chronic cases of infective arthritis in which the causal microbe has not yet been identified. "Fibrositis" is the term to be given to all cases in which the pathological lesion is an inflammation (whether infective or toxic) of the white fibrous tissue of the body—a conception that is far from novel, for it was entertained by Craigie early in the nineteenth century. Either joints, nerves, or muscles may be the apparent seat of this fibrositis. Further explaining the arrangement of their subject matter, the authors divide it into three main portions, namely: (1) Infective or toxic fibrositis, (2) traumatic fibrositis, and (3) villous synovitis of the hip and knee, and sacro-iliac relaxation. The first of these groups again has three subdivisions—articular fibrositis or chronic articular rheumatism, myofibrositis or muscular rheumatism, and neurofibrositis or neuralgic rheumatism. The second group also has three subdivisions; these are subacute rheumatic synovitis, "rheumatic" bursitis, and traumatic muscular fibrositis. Thus it appears that they would throw out the popular term "chronic rheumatism" altogether, substituting for it the name "fibrositis," with its aforementioned subdivisions. Their classification, therefore, takes no account of the diverse causal factors of fibrositis, but rests solely upon the anatomical pathology of its various forms.

The experience of Dr. Llewellyn at Bath, of which he has clearly taken the fullest advantage, enables him to write of the manifold varieties of fibrositis with a first-hand knowledge that few physicians could hope to rival. He tabulates 1,250 cases of fibrositis; for example, in his statistics, 543 of sciatica, and so throughout his series of fibrositic forms. The forty-five chapters of the book deal faithfully with these forms and with their description, etiology, cause, course, and treatment. The photographic illustrations and plates are excellent, and do much to help the text. The text itself is clearly written and full of interesting and original observations. The subject is one that has engaged the casual pens of a host of medical writers. The appearance of so full and authoritative an account of what the public will for many years, no doubt, continue to call "rheumatism," "gout," or "rheumatic gout" indifferently, is a most welcome event for medical men. The book should be widely read, not only for the good sense and novelty of its contents, but also because it contains a mine of information on the cause, diagnosis, and treatment of a group of painful affections so common as to be commonplace—and therefore perhaps unduly neglected—in general medical practice.

PHYSIOLOGY AND HISTOLOGY.

THE first edition of HUXLEY's popular *Lessons in Elementary Physiology*² was published in 1866; the book was ultimately revised and almost rewritten by Michael

¹ *Fibrositis (Gouty, Infective, Traumatic), so-called Chronic Rheumatism, including Villous Synovitis of Knee and Hip, and Sacro-iliac Relaxation.* By Lt Jones Llewellyn, M.B.I.Lond., and A. Bassett Jones, M.B.Lond. London: W. Heinemann. 1915. (Sup. roy. 8vo, pp. 728; 6 plates; 136 figures. 25s. net.)

² *Lessons in Elementary Physiology.* By T. H. Huxley, LL.D., F.R.S. Enlarged and revised edition (6th). London: Macmillan and Co. 1915. (Fcap. 8vo, pp. 619; 185 figures. 4s. 6d.)

Foster. Now Mr. Barcroft restores the work of these men from the dilapidations made by two decades of scientific progress. He has faithfully left untouched any portion of the fabric in which there was not an actual flaw, but where the structure needed repair he has made it thorough, substantial and simple. The results of his handiwork are certain to maintain the long continued popularity of this work, and carry on Huxley's name to yet another generation of students. The textbooks of physiology written for medical students, as all the other tomes on anatomy, medicine, and surgery, have grown to such proportions that they crush his spirit and weigh down his intellect. Mr. Barcroft in the "new Huxley" has given us a book on physiology of the right scope and size not for the public, but for the ordinary medical student. We hope that those students, now destined to be combatants, who live through the war, will on returning to their studies find a less absurd system of education, for the world will want medical men and will be impatient of academic folly. On the subject of ventilation we note that Mr. Barcroft authoritatively states that the air of crowded ill-ventilated rooms contains poisonous exhalations and produces its ill effects through these. He seems to be unaware that the scientific proof of the existence of such poisons has wholly broken down, as evidenced by the researches of first-class workers in Europe and America; the real causes of discomfort and ill health—stagnation, excessive moisture and heat of the atmosphere—are not even mentioned. This is a regrettable defect in a book designed for popular guidance.

Professor FREDERIC T. LEWIS has brought out the second edition of a *Textbook of Histology*,⁵ an enlarged and improved version of Stöhr's book, arranged upon an embryological basis. The account given of the subject is good and full; it is illustrated by 495 figures, which deserve the highest praise for their truth to structural detail and artistic merit. There is a section on drawing at the end of the chapter on microscopical technique, and Professor Lewis recalls therein the fact that the works of Vesalius were illustrated by Jean de Calcar, a pupil of Titian. He cites Robert Hooke, who said: "I endeavoured first to discover the true appearance, and next to make a plain representation of it," and Ruskin, who held that "the real refinement of the outline depends on its truly following the contours." How difficult it is to analyse the truth so as to express it, is shown by the drawings appended of the medullary tube by six students. In the description of the testis the author gives an account of the discovery of the spermatozoa. They were first seen by Dr. Ham, "a man of singular modesty," to whom Leeuwenhoek gives full credit for the discovery in his letters to the Royal Society. "This discerning youth," he says, "visited me, and brought with him in a small vial seminal fluid from a man who had cohabited with a diseased woman; and he stated that after some minutes, when the fluid had become so attenuate that it could be put in a slender glass tube, he had seen living animalcules in it . . . which seemed to him to be provided with tails." Dalenpatius thought that the new individual was enclosed in the spermatozoon, like an insect in its chrysalis. "For while we were observing them attentively a large one threw off its surrounding membrane and appeared naked, showing distinctly the legs, thighs, breasts, and arms. The cast-off skin drawn upward covered the head like a cap, and it was a delightful and incredible sight." This is a gross presentation of the doctrine of preformation of which Sterne made such humorous use in the opening chapter of *Tristram Shandy*. The alternative theory of epigenesis ascribed the origin of the body out of formless substance. Descartes said the new individual "seems to be only a confused mixture of liquors which, serving to leaven one another, become heated; some of their agitated particles dilate and press upon the others, gradually dispersing them in the way necessary to form organs." The careful choice of such interesting matter makes the study of histology far more attractive and of much higher educational value.

⁵ *A Textbook of Histology arranged upon an Embryological Basis*. By Dr. F. T. Lewis and Dr. P. Stöhr. Second edition, being the seventh American edition of Stöhr's Histology. From the fifteenth German edition. Edited by Dr. O. Schultze. Philadelphia: P. Blakiston's Son and Co. 1913. (Roy. 8vo, pp. 650; 495 figures.)

TREATMENT OF FRACTURES.

THE fact that *The Treatment of Fractures*, by Dr. C. L. SCUDDER,⁴ has reached its eighth edition in the space of fifteen years, gives some indication of its popularity. It may fairly be said that no pains have been spared in its production; it contains a most beautiful collection of photographs and skiagrams illustrating not only fractures of the various bones, but in nearly every case plates are given of the most suitable form of splint and its application.

To the British reader a certain number of the methods of treatment are unfamiliar, and he will probably regret to miss, for example, Carr's splint in the description of the treatment of Colles's fracture, but this dissimilarity is no real disadvantage, as it helps to a broader outlook. The author is evidently no great enthusiast for the open treatment of fractures. Most will agree with him when he states that operative treatment should never be undertaken lightly, and should only be resorted to when there are clear indications that the older forms of treatment are not likely to give good results.

Certain sections of the book are especially worthy of mention. There is a most useful article on fractures of the jaw, showing how these difficult cases may be dealt with by wiring and by other methods. Matas's splint, which we have not seen in use in this country, is described and figured. It would seem to be a useful contrivance. It consists of a clamp, one arm holding a mouthpiece which fits the lower jaw, the other a cup which is applied under the chin. When in position, these two arms project directly forward outside the mouth, and are fastened together by a screw. Many fractures of the jaw fall more within the province of the dentist, with his special skill in taking casts and making interdental splints, but Dr. Scudder's observations will be useful to those who have to treat cases of compound fracture of the jaw among the wounded. There are interesting articles on gunshot wounds of bones and the making and application of the various forms of plaster splints. Into the description of the latter a series of photographs is introduced showing every step in the production and application of these splints. The author has devoted considerable attention to the prognosis of the various forms of fracture. In every case a statement is made as to the average length of time in which consolidation may be expected and function regained. The notes should prove of great practical value to the practitioner. In conclusion, it may be said that the book is a most comprehensive account of the subject, and can be most strongly recommended.

CAN LIFE BE EXPLAINED?

DR. R. E. LLOYD is inclined to the opinion that there is a growing number of thoughtful persons whose minds do not regard life as a problem requiring or capable of any final solution. His book, *What is Adaptation?*⁶ was written, he tells us, mainly to determine the direction of opinion on this point. He regards what may be called the teleological enterprise as an outcome of the mechanistic view—that view which regards the universe in general and living organisms in particular as things made, analogous to those of which we ourselves are the makers. This view led first naturally and inevitably to the theological explanation, of which Paley's comparison of man to a watch and the Deity to its maker is a familiar example. When that explanation had ceased to give satisfaction, Darwin suggested natural selection as an alternative. It is a great point with Dr. Lloyd that the selection theory is an attempt to account for adaptation on mechanical lines, but for all that an outcome of the same teleological attitude towards life which produced the theological explanation. For it regards adaptation as a problem assumed to be capable of solution, also as a quality of variable degree, which Dr. Lloyd questions. He thinks that we regard adaptation as a problem only because man does not realize himself as a part of nature and life, so that when he discovers in organisms the same purposive attributes of which he is conscious in his own handiwork

⁴ *The Treatment of Fractures, with Notes upon a Few Common Dislocations*. By C. L. Scudder, M.D. Eighth edition, revised. Philadelphia and London: W. B. Saunders Co. 1915. (Roy. 8vo, pp. 734; 1,057 figures, 25s. net.)

⁶ *What is Adaptation?* By R. E. Lloyd, M.B., D.Sc. (Lond.), Major, Indian Medical Service. London: Longmans, Green, and Co. 1914. (Med. 8vo, pp. 122. 2s. 6d.)

he puts to himself the question: "How is it that life can produce the same kind of results that I myself can produce?" From the author's point of view, which is vitalistic and Bergsonian, "purpose is not a human attribute present in life, but a vital attribute present in man." Once we realize purposive adaptation as an essential and inalienable attribute of life in all forms we shall, the author thinks, cease to wonder at the resemblance between organisms and mechanisms and to regard it as a problem. We shall content ourselves with the endeavour to know more and more about life, but we shall not expect or even desire to explain it. "The problem of life is to know how it is, not how it was made; not to seek for an explanation of it, but to go on explaining it." Dr. Lloyd holds that we are aware of a something beyond the sphere of sense and reason which he calls "supernature," but deprecates the supposition that this something can ever be clearly imagined or understood. His book is well worth reading.

NOTES ON BOOKS.

THE dependence of the modern treatment of lunacy upon Harvey's great discovery is not very easy to establish, but in his *Harveian Oration*⁸ Dr. COUPLAND contrived with some skill to pass from the one to the other, and what he says about insanity is marked by restraint and good sense. He is no fanatical advocate of the universal causation of insanity by drink. It is true that of first attacks of insanity 26.3 in the male and 10.4 in the female occur in persons addicted to drink, but he very properly points out what is usually forgotten—that these figures are of no value unless they are controlled by an analogous census of drinkers who do not become insane. It is rather astonishing to hear from Dr. Coupland that no fewer than one-fifth of the total admissions into public asylums, amounting in all to 20,000 in each year, are known to have suicidal propensities, and it is extraordinary that, although more than 4,000 persons known to be suicidally inclined are admitted in each year, yet only fourteen in each year succeed in carrying out their intention. How much vigilance, care, and anxiety on the part of asylum officials these figures indicate it is difficult to estimate. Dr. Coupland reviews recent legislative proposals for treating insane persons without certifying them, and shows without difficulty that the "stigma" of certification is wrongly placed. The real "stigma" is upon the insanity.

MEDICAL AND SURGICAL APPLIANCES.

An Artificial Arm.

AT a recent meeting of the Swansea Division of the British Medical Association, Dr. W. L. Griffiths, surgeon to the Swansea General and Eye Hospital, demonstrated an artificial limb for cases in which the arm has been amputated below the elbow. It was, he said, the invention of Mr. Thomas Williams of Dunvant, who forty years ago had undergone amputation of the right forearm four inches below the tip of the olecranon process, but had since been able to earn his living as a collier, as a mechanic, and in other ways. The construction of the limb is illustrated in the diagram, which is taken from the patent specification. The forearm, A, is made in one piece of stout or stiff leather, and the casing for the upper arm is formed in two pieces, B, C, of soft or pliable leather attached to the forearm. These pieces are eyeletted and laced together so as to clasp the upper arm, soft tongues, D, E, being provided under the laces, F, if desired. This arrangement, besides giving more comfort, renders it possible in most cases for the wearer to attach the appliance in position without assistance. Within the wrist of the forearm casing is a block (G, Fig. 2) of wood or other suitable material, over the outer part of which is firmly fitted and secured a dome-shaped metal cap or holder, H, having a central hole or socket, J, screw-threaded internally. A correspondingly threaded plug, K, provided with an outer flange, L, is adapted to screw into this socket. This plug is centrally bored so that the shank, M, of the C-shaped hook can freely pass therethrough. The part of the bore nearest to the arm has an enlarged part, N, similar to a stuffing box, to receive a spring, O, which is coiled around the end of the shank when placed therein. This spring is com-

pressed between abutments formed by the shoulder, P, in the plug, and a nut or cap, Q, which is screwed on to the end of the shank, and is small enough to enter the space N. The plug, K, is then screwed into the socket, J, until the flange, L, meets its seating, R, and the appliance is ready for use. The hook, with its shank, M, is free to revolve axially in the plug, K, after the latter is screwed home, but is prevented from doing so too freely owing to the friction on the ends of the spring and between the base of the hook and its abutment, S. When a sudden pull comes upon the hook, the spring is further compressed and lessens the jar. Dr. Griffiths said that the chief points of interest were the shape and action of the hook, and the mode of attachment to the stump. The hook was convenient for using tools, for lifting and for pushing. The attachment of the artificial limb by means of soft leather flaps laced round the upper arm taking their grip above

the condyles of the humerus, allowed free movement of the elbow-joint. The experience of the inventor, who had been using the arm for forty years, showed that there was no risk of pressure sores; the skin was freely movable over the deeper tissues, and it was not appreciably thickened. Mr. Williams could use a pick and shovel, could lift a weight of 56 lb., could swing a 14 lb. sledge hammer, could use a scythe, could plough, could pitch hay, and do any other work of an agricultural labourer, and could work as a collier, a mechanic, and a carpenter. Dr. Griffiths expressed the opinion, in which members present concurred, that it was the best artificial arm yet designed for a case in which the forearm has been amputated below the elbow.

THE MILITARY MEDICAL SERVICES IN 1915.

IN the *BRITISH MEDICAL JOURNAL* of January 2nd, 1915, was published an article on the military medical services in 1914, with special reference to the first five months of war, and the work and losses of these services under arms. The present article continues the history of these services during twelve months of war in 1915.

THE ARMY.

Last year's note included two tables, giving the strength of the R.A.M.C. in January and in December, 1914, respectively, showing the great expansion of the R.A.M.C. to meet the needs of war. The strength of that service had increased between July and December, chiefly by the employment of temporary officers, by about two-fifths, or roughly, including Territorials and Reserve medical officers, from somewhat over 3,000 to a good deal over 5,000.

These two tables are now reproduced (slightly corrected), along with a third, six months later, compiled from the monthly *Army List* of June, 1915, the last available to the

⁸ *The Harveian Oration, 1915.* By Sydney Coupland, M.D. London: Cassell and Co. 1915.

general public, which shows a much greater expansion, after nearly a year of war, to well over 7,000.

*Strength of the R.A.M.C.**

	January, 1914.	December, 1914.	June, 1915.
<i>R.A.M.C. Regulars.</i>			
Surgeon Generals	12	12	22
Colonels	29	35	59
Lieut.-Colonels	130	151	254
Majors	312	351	245
Captains	422	399	488
Lieutenants	129	121	1
Total	1,054	1,099	1,107
<i>Retired Officers employed</i>			
	65	102	149
<i>Special Reserve.</i>			
Lieut.-Colonels	—	1	1
Majors	15	10	9
Captains	26	60	73
Lieutenants	143	590	626
Total	184	661	709
<i>Temporary Officers.</i>			
Colonels	—	7	14
Lieut.-Colonels	—	7	33
Majors	—	10	51
Captains	—	41	122
Lieutenants	—	1,073	2,477
Total	—	1,138	2,697
<i>Territorials, all Ranks.</i>			
Regimental	567	640	703
Field ambulances	363	609	808
General hospitals	201	745	848
Sanitary service	116	119	169
Clearing hospitals	—	31	93
Total	1,709	2,144	2,621

* These figures should be considered absolutely accurate, but will be found correct within a few units in each case. There is a certain amount of overlapping. In some cases an officer's name appears twice over, in different places.

Summary.

	January, 1914.	December, 1914.	June 1915.
<i>R.A.M.C.</i>			
Regulars	1,054	1,099	1,107
Retired officers	65	102	149
Special Reserve	184	661	709
Temporary officers	—	1,138	2,697
Territorials	1,709	2,144	2,621
Total	3,012	5,144	7,283

It will be seen that, though there had been no new admissions to the R.A.M.C. between December, 1914, and June, 1915, while many casualties have occurred, the numbers have not fallen but have slightly increased. This is due to the absorption into the active list of a number of retired officers from the reserve. The one lieutenant shown in June, 1915, is a reserve officer. Senior officers who have attained the age for compulsory retirement, and those who have completed the regular tour of service in the administrative ranks, have also been retained on the active list. The numerous recent promotions from the rank of lieutenant to that of captain, among the temporary officers and those of the Special Reserve, were still shown as lieutenants in June.

The June *Army List* also shows 114 medical officers in the Canadian forces and three in the Newfoundland contingent. The details of the Australian and New Zealand forces are not given.

Though the *Army Lists* of a later date than June, 1915,

are not available for comparison, we can refer to an official statement of strength in November, which must be at least approximately accurate up to that date. On November 9th Mr. Tennant, Under Secretary of State for War, stated in the House of Commons that the strength of the R.A.M.C. up to that date, including regulars, retired officers re-employed, Special Reserve, temporary officers, and Territorials, was 9,626, of whom 2,474 were Territorials. (In a similar statement made in the House on May 19th the number of Territorials was given as 2,122, and the total number as 7,027.)

It must be noted that the figures given above—9,626 medical officers—do not appear to include the medical department of the Canadian, New Zealand, and Australian forces—say perhaps 400 in all—or the Indian Medical Service—nearly a thousand. To these may also be added the strength of the medical department of the navy—say 1,000—making a total of, roughly, some 12,000 medical officers employed in the different fighting services.

Since November 9th a further considerable number of temporary lieutenants have been gazetted to the R.A.M.C., while a few have resigned their commissions. These changes have probably brought up the total number of officers in the various branches of the R.A.M.C. to over 10,000 by the end of the year. Many of the Canadian medical officers have also been gazetted temporarily to the R.A.M.C. On the other hand, the number of Territorial medical officers shown in the June *Army List* (2,621) is larger than the figure given for November 9th (2,474).

Not all of these medical officers are giving full-time service. The Regulars, Special Reserve, and temporary officers are of course doing so. So are all the Territorial medical officers serving with regiments, with field ambulances, and with clearing stations. In the Territorial general hospitals, however, as a rule, only the commanding officer and registrar are whole-time officers; the majority of the staff are giving part-time service only. Many individuals have been seconded for service abroad, and thus are giving their whole time; but such officers have presumably been replaced and struck off the strength of their own hospitals. On the other hand, a number of medical men are serving under the British Red Cross, chiefly in hospitals at home and abroad; and while some of them hold temporary commissions, and so are included in the statistics given above, the majority are not so commissioned.

KILLED OR DIED OF WOUNDS OR DISEASE.

The number of medical officers killed in action, including those who died of wounds or went down with the ships on which they were serving, in 1914, during five months of war, was 46. Of these, 27 belonged to the R.A.M.C. (Regulars 21, Special Reserve 1, Territorials 1, and temporary officers 4), 13 to the navy (active list 9, reserve 2, R.N.V.R. 1, and 1 temporary), 2 to the I.M.S., 1 to the West African Medical Staff, and 1 to the Australian force in New Guinea, while 2 were serving as combatants. The two last, of course, though medical men, were not medical officers.

In 1915 the number killed is, as might be expected, much larger, totalling over 100. No fewer than 15 fell in the advance on September 25th and subsequent days and the ensuing German counter-attacks. The chief incidence of loss in the past year, however, has fallen, not on the Regulars, but on the Territorials and the temporary officers. The figures are as follows:

Royal Navy (active list 9, R.N.V.R. 2, temporary 3)	14
R.A.M.C. (Regulars 8, Special Reserve 6, Territorials 12, temporary 36)	62
Colonial Forces (Canada 2, Australia 5, New Zealand 1)	8
Indian Medical Service	5
Colonial Services	5
Mercantile Marine	3
Combatants	13

In addition to those actually killed, 21 have died of disease or by accident while serving abroad, or very soon after being invalided home, making a total roll of honour of considerably over 120.

The names of those killed are as follows. It is possible that one or two names may have been omitted. If so, we shall be glad to receive information.

R.A.M.C., Regulars.

In France and Flanders: Colonel E. O. Wight; Major F. G. Richards; Captains H. V. B. Byatt, J. F. Gwynne, and E. C. Deane; and Lieutenant P. M. J. Power.

In the Dardanelles: Colonel N. Manders.

In Mesopotamia: Captain M. Burneth.

R.A.M.C., Special Reserve.

In France and Flanders: Captains H. C. Storrie and S. F. M. Cesari; Lieutenants W. T. McCurry, G. M. Chapman, E. Faulks, and R. Montgomery.

R.A.M.C.(T.F.).

In France: Captain E. L. Giblin.
In the Dardanelles: Lieutenant-Colonel W. B. Pritchard; Majors J. C. Taylor and D. R. Taylor; Captains A. Keilas and W. R. Roberts; and Lieutenants P. T. Warren and A. B. Thompson; also four lost in the transport *Royal Edward* in the Aegean Sea: Lieutenant-Colonel J. H. Dauber, Major J. Mowat, Captain C. B. Marshall, and Lieutenant T. Hayhurst.

R.A.M.C., Temporary.

In France and Flanders: Captains J. N. Armstrong, A. E. Bullock, E. W. Carrington, T. H. S. Bell, G. I. Grant, A. G. Miller, and J. H. Meers; Lieutenants D. Campbell, D. O. Turnbull, J. R. Waddy, E. Stratford, H. W. Goodden, J. A. MacMahon, M. Pern, G. H. Lunan, D. G. Watson, G. M. M. Fleming, G. Macallum, J. C. Hawkes, K. Robinson, C. M. Harris, E. T. Nangle, J. R. Spensley, E. H. P. Brunton, T. J. Latham, M. Mackenzie, J. R. G. Garbutt, A. Hegarty, and O. G. Muirness.

In the Dardanelles: Captain A. Graham; Lieutenants J. Cattanach, T. A. Peel, J. Clarke, F. J. Wisley, J. W. Parker, and F. H. Young (in the transport *Marquette*).

Canadians.

In France and Flanders: Major W. P. Dillon and Captain G. O. Glidden.

Australians.

In the Dardanelles: Majors S. J. Richards and F. M. Johnson; Captains G. C. Matthison, K. Levi, and G. P. J. Luther.

New Zealanders.

In the Dardanelles: Lieutenant-Colonel C. E. Thomas.

The names of those who have died on service overseas, or soon after reaching home invalided from service, are:

R.A.M.C., Regulars: Major C. E. Fleming, Glasgow; Captains A. A. Sutcliffe and S. Field, both as prisoners of war at Wittenberg, in Saxony.
R.A.M.C.(T.F.): Lieutenant-Colonels G. A. Edsell, Surbiton, and A. A. Ross, London; Majors A. Hilton, Egypt, and W. A. Malcolm, Malta; Captains G. W. Buxton and W. E. Rielly, Dardanelles.

R.A.M.C. (Temporary): Captain J. F. Fairley, France; Lieutenants E. A. Wright, Alexandria; W. R. Pryn, France (accident); S. B. Walsh, France; E. D. Parsons, London; J. McGowan, Malta, and J. C. Bell and B. C. Letts, Alexandria.

Australians: Captain A. Verge, Alexandria.

New Zealanders: Colonel F. C. Batchelor, Dunedin; Major T. C. Savage and Captain J. A. T. Bell, Egypt.

As was the case last year, and as is naturally the case, the great majority of the officers killed were of the junior ranks. In the R.A.M.C., two full colonels and one major were killed, of the Territorials two lieutenant-colonels and three majors, one lieutenant-colonel in the New Zealand contingent, two majors in that from Australia, one major in the I.M.S., and one lieutenant-colonel and one major serving as combatants.

SONS OF MEDICAL MEN.

A very large number of sons of medical men have fallen in the war, as may be seen in the pages of this JOURNAL during the past six months, during which over two hundred have been recorded. A very large number also fell during the first eleven months of the war, before the JOURNAL began to insert these notes. Many cases must have escaped notice, especially among the colonial contingents.

MEDICAL STUDENTS.

The number of medical students recorded as killed is not so large, but in this case also, even more than in that of sons of the profession, the information available is very incomplete. During the past six months over fifty such cases have been recorded in the JOURNAL, not counting those medical students who were also sons of medical men, but including those recently reported from Trinity College, Dublin.

MEDICAL MEN AND DENTISTS KILLED OR DIED OF WOUNDS WHILST SERVING AS COMBATANTS.

The following is a list, as complete as we have been able to make it, of medical men and dentists holding commissions as combatants who have been killed or died of wounds since the beginning of the war. The list is very possibly incomplete, and we shall be obliged if relatives of any other medical men who have been killed or died of wounds while holding commissions as combatants would communicate with us. We should also be glad to receive particulars of any medical man who may have been killed or died of wounds whilst serving as a combatant but not holding a commission. The names in the list are arranged in alphabetical order:

Medical Practitioners.

F. M. Bingham, L.R.C.P., M.R.C.S., Captain 5th King's Own Lancaster Regiment, Flanders, May 22nd, 1915.

A. C. Clifford, L.R.C.P., M.R.C.S., Second Lieutenant 3rd Dragoon Guards, Ypres, Flanders, June 1st, 1915.

A. Corley, M.D., Captain 11th Australian Infantry, Dardanelles.

S. N. Crowther, L.R.C.P., M.B.C.S., dispatch rider, Flanders, October 18th, 1914.

S. C. Huddleston, M.B.Edin., Second Lieutenant 3rd Black Watch, France, January 25th, 1915.

B. M. Hughes, L.R.C.P., M.R.C.S., Captain 1/4th Norfolk, Dardanelles, September 15th, 1915.

H. T. Hunter, M.B.Durh., Captain 6th Northumberland Fusiliers, Ypres, Flanders, April 26th, 1915.

J. W. Jessop, L.R.C.P., M.R.C.S., Lieutenant-Colonel 4th Lincoln, France, June, 1915.

T. S. Lukis, M.D.Lond., Lieutenant 13th London Regiment, France, March 15th, 1915.

W. E. Maitland, M.B.Glasg., Lieutenant 3rd Seaforth Highlanders, France, December, 1914.

E. M. Ridge, F.R.C.S., Sub-Lieutenant R.N.V.R., Antwerp, October, 1914.

A. Wallace, M.B.Edin., Captain 1/4th K.O.S. Borderers, Dardanelles, July 12th, 1915.

Dentists.

J. J. Dykes, L.R.C.P. and S.Edin., L.R.F.P.S., L.D.S., Captain 1/5th K.O.S. Borderers, Dardanelles, July, 1915.

J. Morham, L.R.C.P. and S.Edin., L.R.F.P.S., L.D.S., R.C.S.Edin., Captain 4th Royal Scots (missing), Dardanelles, September, 1915.

H. B. Neely, L.D.S., 2nd Lieutenant 1st Suffolk, Ypres, Flanders, April 25th, 1915.

WOUNDED.

The number of medical officers whose names have appeared in the casualty lists as wounded during the year is considerably over two hundred. It is probable that the figures given are not absolutely correct, but they are approximately so. In a few cases the same officer has been more than once returned as wounded. The numbers recorded can be shown most easily and clearly in a tabular form, for all the services together.

	France and Flanders.	Dardanelles	Balkans.	Persian Gulf.	East Africa.	West Africa.	India.	Total.
R.A.M.C.	19	4	—	1	—	—	—	26
R.A.M.C.(T.F.)	24	25	—	—	—	—	—	49

I.M.S.	3	3	—	10	—	1	1	18
West African Service	—	—	—	—	—	1	—	1
Total	135	72	—	14	—	2	1	224

HONOURS.

A fair share of honours has fallen to the medical services during the year, chiefly to the regular R.A.M.C. The greatest honour of all—the Victoria Cross—has been bestowed on three medical officers in 1915, besides one, the late Captain Ranken (killed in action) in 1914: temporary Lieutenant (now Major) Martin-Leake; Captain Scrimgeour of the Canadian force, and temporary Lieutenant Maling. Major Martin-Leake had won the V.C. in South Africa, and in February, 1915, received a clasp to his Cross. Whether a clasp to the V.C. has ever been awarded before seems somewhat doubtful, but however this may be, it is certain that such a grant is a very rare honour.

Honours also can be most clearly shown in a table for all the medical services together.

	V.C.	K.C.B.	C.B.	D.S.O.	Military Cross	D.S. Cross	K.C.M.G.	C.M.G.	Foreign.	Total.
R.A.M.C.	—	1	17	27	23	—	—	20	1	88
R.A.M.C.(T.F.)	—	—	—	1	3	—	—	1	2	7
R.A.M.C.(S.R.)	—	—	—	2	9	—	—	—	—	11
R.A.M.C. (temporary)	1	—	3	5	23	—	3	—	1	40
Canadians	1	—	1	1	1	—	—	2	—	6
Australians	—	—	1	1	—	—	—	1	—	3
New Zealanders	—	—	1	2	—	—	—	1	—	4
R.N.	—	—	—	3	—	2	—	—	4	9
I.M.S.	—	—	2	3	3	—	—	3	—	11
Total	3	1	25	45	64	2	3	28	8	179

The honours gazetted on January 1st, 1916, are not included in the above table.

PROMOTIONS.

On March 1st a large number of promotions were made in the regular R.A.M.C.—68 lieutenant-colonels were promoted to the rank of full colonel, 171 majors to that of lieutenant-colonel, while all the lieutenants were promoted to the rank of captain. Later, all temporary lieutenants were granted the rank of captain after one year's service, while lieutenants of the Special Reserve and Territorial Force have been granted that rank after six months' embodied service. Ten brevet promotions have also been given in the R.A.M.C. and 5 in the I.M.S.

NURSES.

The members of the nursing service are not ordinarily employed under fire, and, as far as we know, no nurse has actually been killed in this way. But 10 were lost in the transport *Marquette* in the Aegean Sea and 1 in the hospital ship *Anglia* in the Channel. These ladies have in their way lost their lives in action just as much as if they had fallen in the firing line. Eleven others, at least, have died on service.

THE INDIAN MEDICAL SERVICE.

This service has maintained its normal strength of a little under eight hundred throughout. Early in 1915 the men who passed in July, 1914, joined the active list. An examination was held in July, 1915, at which eight candidates were accepted, and a few of the temporary lieutenants have been gazetted to the permanent list.

A large addition has, however, been made by the employment of temporary lieutenants, chiefly Indian qualified men, and of retired officers re-employed. It may be remarked that while only five retired I.M.S. officers are shown as employed in the *Army List* of January, 1915, there were actually nearly fifty such officers serving before the end of 1914.

The following table shows the strength of the I.M.S.:

	January, 1914	January, 1915.	June, 1915.
Active list	770	788	785
Temporary officers	—	5	62
Retired officers re-employed	—	5	49
Total	770	792	896

Since June the number of temporary officers has increased to 130. There are also some thirty retired officers, re-employed in India, all or most of them in civil appointments, who are not included in the above table.

The temporary officers appointed include one major and four captains; the rest are all lieutenants. Among them are two officers who had resigned the service in their first few years, and who have now temporarily rejoined. A third officer, who had likewise resigned, has been reappointed on the permanent list. The temporary major is an officer who had served for nearly thirty years in the Indian army, and had retired after the usual period of command of a regiment. After retirement he took up the study of medicine, and qualified shortly before the war.

In normal times the number of officers of the I.M.S. in civil employ is nearly 500, while nearly 300 are ordinarily on military duty. The civil branch of the I.M.S. has always been looked on as a reserve for the army in time of stress, and fully one half of the officers usually in civil employ have been on military duty during the year. Members of the I.M.S. have been on active service, during 1915, in France and Flanders, in the Dardanelles, Egypt, the Persian Gulf, East Africa, West Africa, and on the Indian frontier. A number have also been employed in base hospitals in the south of England and in hospital ships. Some of the Indian base hospitals in England have recently been closed; the others will also be closed before long, as it is reported that most of the Indian troops have left France for the East.

Two members of the I.M.S. were killed in action in 1914—Major P. P. Atal and Captain K. I. Singh. Five more have fallen in 1915—Major J. Woods and Lieutenant J. P. Walsh in Flanders, Captain M. F. Reaney in the Dardanelles, Captain F. S. Smith and Lieutenant M. B. Patel in the battle of Ctesiphon, in Mesopotamia. Lieutenant

Patel has been the first of the temporary officers of the I.M.S. to fall, also the first Parsi, though the third Indian-born member of the I.M.S. who has been killed in action. Two other officers have lost their lives on active service—Major J. O'Leary, drowned at Ismailia, and Lieutenant T. B. Paul, who died in the Persian Gulf Expedition. Two retired officers also died on duty during the year while employed in the base hospitals for Indian troops—Lieutenant-Colonel E. Lawrie at Brighton, and Lieutenant-Colonel L. F. Childe, who was serving in the Lady Hardinge Hospital at Brockenhurst.

Eighteen others have been wounded—ten in Turkish Arabia, including five in the battle of Ctesiphon, three in the Dardanelles, three in Flanders, and one each in West Africa and on the Indian Frontier.

Of war honours, the I.M.S. have received eleven—two C.B.'s, three D.S.O.'s, three Military Crosses, and three C.M.G.'s, besides five brevets.

THE COLONIAL SERVICES.

The only colonial medical service which has officially taken part in the war is the West African Medical Staff, several members of which have been serving in the Cameroons. This service lost one officer killed in 1914, in the past year one officer has been wounded. Several retired officers are now temporarily serving in the R.A.M.C.

Two members of the service—Drs. F. J. A. Baldwin and A. W. H. Grant—were also lost in the *Falaba*, torpedoed in the Irish Sea on March 28th.

Another colonial medical service, however, that of the Straits Settlements and Federated Malay States, has lost heavily, no less than three of their members having been killed in the mutiny at Singapore last February, two of them while serving with volunteer troops. These three were Dr. E. D. Whittle, Colonial Surgeon, Dr. P. N. Gerrard, Malay States Volunteer Rifles, and Lieutenant A. F. Legge, Singapore Volunteer Medical Company.

THE ROYAL NAVY.

The following table shows the strength of the medical departments of the navy for January, 1914, January, 1915, and July, 1915, as given in the *Navy Lists*, respectively. Unlike the R.A.M.C., the naval medical department has not required to expand, and has not expanded, to any very great extent during the war; the number of temporary and reserve officers is barely equal to that of the regular active list.

	January, 1914.	January, 1915.	July, 1915.
Active list:			
Surgeon-Generals... ..	6	6	6
Deputy Surgeon-Generals	10	11	11
Fleet Surgeons	162	178	182
Staff Surgeons	171	171	162
Surgeons	159	158	150
	523	524	511
Temporary:			
Consultants... ..	—	11	10
Staff Surgeons	—	—	1
Surgeons	—	289	383
	—	300	394
R.N.V.R.:			
Staff Surgeons	11	—	21
Surgeons	53	6	71
Surgeon Probationers	—	82	37
	64	88	114
Reserve	10	9	7
Total	597	921	1,026

There are also shown in the *Navy Lists* a little over 400 appointments as surgeon and agent, at small seaports round the coast. These are not whole-time posts; the duties are light and the remuneration small. They are mostly held by private practitioners; a few are filled by retired naval medical officers.

Losses.—The number of naval medical officers killed during the year is 14, as follows:

Fleet Surgeon G. Taylor, and Surgeons W. M. S. Miller and S. Hibbert, lost in H.M.S. *Formidable*, in the Channel, on January 1st.
Surgeon V. L. Matthews, lost in H.M.S. *Viktor* off the North of Ireland, about January 20th.
Staff Surgeon W. G. Moore Anderson and Surgeon-Probationer R. O'C. Redmond, lost in H.M.S. *Clan Macnaghten*, in the North Sea, in February.
Surgeon F. W. Quirke, lost in H.M.S. *Princess Irene*, blown up at Sheerness, on May 27th.
Fleet Surgeon G. A. Forrester, killed on H.M.S. *Implacable*, April 25th, and Fleet Surgeon G. A. Waters, lost in H.M.S. *Goliath* on May 12th, both in the Dardanelles.
Surgeon T. L. G. Stewart (June 14th), Surgeon F. H. Rees (June 1st), and Surgeon F. J. Humphreys (September 5th), killed in the Dardanelles.
Staff Surgeon A. O. Hooper and Surgeon D. W. K. Moody, killed on H.M.S. *Natal*, blown up on December 30th.
Temporary Surgeon D. R. B. Sivright, died at the Dardanelles.

Of these officers, Surgeon Hibbert and Surgeon-Probationer Redmond belonged to the R.N.V.R.; Surgeons Stewart, Humphreys, Moody, and Sivright were temporary Surgeons; the other ten were on the active list.

Wounded: Six naval medical officers have been wounded, all in the Dardanelles.

Honours granted have not been many; they may be seen in the table above.

THE MERCANTILE MARINE.

Three medical officers of the mercantile marine have lost their lives in ships torpedoed and sunk by the enemy, Drs. J. Macdermott and J. Garry in the *Lusitania* on May 7th and Dr. Everett in the *Persia* on December 30th. It would seem probable that other ships' surgeons must have perished in some of the numerous vessels sunk by submarines, but we have not noticed the names of any others recorded.

Miss E. S. Impey, M.B., a lady doctor going out to join the Dufferin Hospital for Women at Lahore, appears also to have been lost in the *Persia*.

MOTORS FOR MEDICAL MEN.

By H. MASSAC BUIST.

WAR EXPERIENCE AND NEW DESIGNS.

At the turn of the year it is natural to take stock of the motor situation, particularly as concerns the prospects of obtaining vehicles in the future in face of the continuance of the war. As regards the British industry, it is plain that, save for releasing a limited portion of the heavy vehicle production for supply of firms concerned in war work, and for a few examples of light cars, chiefly of the assembled variety, all the resources of the factories will continue indefinitely to be fully employed on Government work.

Incidentally, the medical man will doubtless be aware that during the five months that have elapsed since last this topic was touched on in these pages a large amount of experience has been gained at the front with British-made light cars of the comparatively few well-established makes, including, notably, the Singer machines. The French also now make extensive use of light cars in the war area, running them almost invariably with open exhausts.

None of these machines is spared in the least degree, and the test is a hard one, not only of engine revolutions and reliability in the ordinary sense, but also of every part of the chassis. Much cobble or *pavé* has to be traversed in the vicinity of the towns, while in the open the roads are very much broken up. It is impossible for large numbers of vehicles to be submitted to these conditions of use for month after month without the manufacturers of them learning lessons which will ensure their being able to make light cars after the war which shall be as absolutely dependable for the medical man's daily and nightly service all the year round as middle-size cars, such as Rovers, De Dions, Swifts, and the like, have been for years.

LIGHT CAR TENDENCIES.

Turning to light-car progress in quite another direction, namely, across the Atlantic, we note in such comparatively new propositions as the Saxon machine that in the New World they are using wider axles for light cars than is the current practice in Europe, and this without

appreciably increasing the weight factor. This development is likely to be followed in some degree in this country in that these wider axles are a natural corollary of the tendency that has been manifest here to lengthen light-car wheelbases. It is not only that better riding is obtained; with the wider axle there is besides the gain of enhanced lateral stability. This is of especial importance in the light car. Taken with the fact, proved by war service rendered by the British-built Singer light car, that the change-speed gear mechanism can be satisfactorily incorporated in the back axle details, even as for years past has been done in some of the middle-size and large cars, such as the Overland, it will be realized that the problem of making a highly efficient and speedy light car to hold the road is one already far on the way towards solution.

In the meantime the medical man would be wise to bear in mind that, while many varieties of light cars, assembled and otherwise, are available to him to-day, nevertheless the pick of the output is being taken, as it ought to be taken, by the Government for war service. For the rest, production is restricted by the necessity for the shops turning out other war requisites besides light cars.

As far as we can see into 1916, the only light cars likely to be available in large numbers are of the imported or of the assembled varieties; though by careful investigation here and there it will be possible to secure on occasion examples of what one might call the more classic makes that have been tried in war service and not found wanting.

A CAR TO BE LUBRICATED ONCE IN SIX MONTHS.

Turning next to middle-size cars which, from the inception of the motor movement to date, have rendered the medical profession the greatest amount and variety of service, we find that no such thing as a 1916 model has yet been announced by the British manufacturers. A few 1915 examples can be unearthed out of stock, and, of course, to the number of used cars that are being offered for sale as the strain of the war becomes more and more apparent on folks' finances, there would appear to be no end.

But there has lately been brought forward by the firm of J. B. Ferguson, of Belfast, a design for a middle-size motor-car which, as a design, is of considerable interest to the medical profession. It represents the conception of a machine of refinement of working which shall need the minimum of attention and which will nevertheless be so adequately oiled and lubricated throughout that there will be the minimum of wear on the parts, therefore the maximum of use will be obtainable. This will be called the 14-20 horse-power Fergus car. The first example has been on the road some time. I understand that in face of the impossibility of getting the type made in any numbers here the notion is to get most of the parts manufactured in America, each by a specialist.

The scheme embraces a four-cylinder 14-20 h.p. monobloc engine, in combination with a worm-driven back axle and cantilever springs. All the springs are leather bound, to ensure their retention of the lubrication, the feed of which is automatic, and to protect the leaves from damp. The side members of the frame are quite original, being of girder formation, combining great rigidity with lightness.

There are here no inaccessible parts for the owner to lubricate; consequently, no vital parts can be neglected in this connexion. In the average car of to-day there are anything up to eighty parts to attend to in the way of lubrication, many of them daily, whereas in the Fergus car there are only eleven parts to which lubrication has to be supplied, and each of these needs attention once in every six months only.

This is really studying the man who wants to look after his own car. Apart from trouble saving, automatic lubrication is preferable on the grounds of effectiveness. In turn this represents economy of wear and adjustments, and consequent reduction of repair bills to the minimum, it being assumed, of course, that each part is correctly designed for the work it is called on to do.

The frames, which are to be made at Messrs. Ferguson's own works by special presses, reveal that the designing talent employed is sound. Though of extremely light appearance, the combination of steel girder and lattice work design ingeniously provides strength precisely where

It is needed, the shape being determined by the conditions arising from the tension stresses at this point and the compression ones at that.

A NEW YEAR AMERICAN NOVELTY.

As far as concerns vehicles not used wholly for business purposes, Mr. McKenna's autumn budget largely altered the prices of American cars in this country, though, so far, those who import these vehicles in parts, and assemble them here at little cost, successfully escape all but a fraction of the duty.

As from January 9th, 1916, one of the best-known and largest American motor firms—Willys-Overland—which has already established a reputation here, is putting on the market in this country a new model car, which, though imported completely assembled, will cost only £225 for the five-seater and £220 for the two-seater, both prices being inclusive of the full duty of 33½ per cent., which represents a contribution to the Exchequer of over £40 per vehicle.

Thus the price, including duty, is brought within the range of a very large public, while no less important is the fact that the whole plan of it is essentially European and not nominally so. The four-cylinder engine comes under the 4 guinea tax, being a fraction under 80 mm. in the bore with a stroke measurement of 127 mm. The cylinders are cast in a block, the valves being all on one side.

The engine might have been designed in Coventry. It is nominally of 12 h.p. and actually capable of developing over 20 h.p., so that here we have an American car rated according to European practice, as distinct from the American fashion of rating the motor at the very utmost power it is capable of developing for a brief spell.

The chassis is of European pattern, also in having cantilever rear springs, while the three-speed gear box is combined with the back axle on a system widely tested and found successful for many years. When the lower indirect speeds are in service, this scheme represents a reduction of engine torque to a quarter the amount experienced when the gear box is at the forward end of the propeller shaft. The weight of the complete vehicle comes within the ton limit, and the tyres are proportionately large. The equipment is complete, from electrical engine-starter and lighting system, embracing dashboard inspection lamp, down to detachable rims, including a spare hood cover, gauges, pockets, foot-rests, and so on. Of course, the gear-control and hand-brake levers are worked by the left hand, because they are centrally situated to the saving of weight and attaining a better leverage. I have seen the car, which will be widely announced in the general press from now onwards.

At the moment this is about all there is in the motoring situation calculated to be of interest to the medical man.

TENURE OF MEDICAL OFFICERS OF HEALTH.

SIR PHILIP MAGNUS, M.P. for the University of London, has maintained his interest in the subject of obtaining security of tenure for medical officers of health, which he took up at the request of the British Medical Association. Last February, in consequence of his representations, the then president of the Local Government Board, Mr. Herbert Samuel,¹ stated that he was prepared to issue an order providing that in the case of future appointments of whole-time officers (medical officers of health, and sanitary inspectors), whose appointments are subject to regulations made by the Local Government Board, the officer shall continue to hold office until he is removed by the local authority with the Board's consent, or is removed by the Board. He also undertook to suggest to local authorities that all officers holding temporary whole-time appointments should be reappointed under the new terms. Sir Philip Magnus has recently approached Mr. Samuel's successor, and the following correspondence has passed:

Local Government Board, Whitehall, S.W.,
December 30th, 1915.

My dear Magnus,

In accordance with the decision of my predecessor, which was contained in his letter to you of February last, my Department have prepared an Order giving security of tenure to whole-time medical officers of health and inspectors of nuisances appointed in the future.

I entirely agree with the decision at which Mr. Samuel arrived, and am strongly in favour of security of tenure for these officers, but I must confess that my own feeling is that the present is hardly the most appropriate time for the issue of such an Order, in view of the fact that so many of our best men have given up local work for service with the army or navy, and that the conditions are now quite abnormal.

Perhaps you would kindly let me know what your views are, and whether in the circumstances you would see any objection to the issue of the Order being further postponed.

Yours sincerely,
(Signed) WALTER H. LONG.

Sir Philip Magnus, M.P.

16, Gloucester Terrace, Hyde Park,
January 4th, 1916.

Dear Mr. Long,

I have carefully considered your letter of December 30th last, for which I am much obliged.

I agree with you that the present time may not be opportune for the issue of the proposed order of your Board giving security of tenure to whole-time medical officers of health and inspectors of nuisances appointed in the future.

I understand that your reasons for postponing the order are:

First, because many of the best men who previously held these posts are now serving in the army or navy, and that it is consequently undesirable that their places should be permanently filled by other applicants in their absence.

Secondly, because even when vacancies occur through death or resignation, such vacancies cannot be so efficiently filled at a time when competition for the appointments is necessarily restricted owing to the absence of many competent men who might be applicants.

These reasons seem to me quite sound, and I may add that the complaint has already reached me that advertisements have appeared in the press for the appointment by Local Authorities of medical officers to fill posts which have been vacated by those who are now serving in the army, and it is contended that these positions should be only temporarily filled, in order to enable the absent officers to resume their former duties should they so desire when the war is over.

In these circumstances, therefore, it certainly seems to me advisable that the issue of the Board's order should be further postponed.

I am, dear Mr. Long,
Yours very faithfully,
(Signed) PHILIP MAGNUS.

The Right Hon. Walter Long, M.P.,
President of the Local Government Board.

The public health service and the medical profession generally are greatly indebted to Sir Philip Magnus for his unwearied efforts to obtain the removal of the present disabilities of medical officers of health as regards security of tenure and other matters, and will, we have no doubt, agree with the general tenour of the letter with which the correspondence has at present closed.

ROYAL MEDICAL BENEVOLENT FUND.

(Continued from page 66.)

The following is a continuation of the summary of cases relieved by the Committee at its meeting on December 14th, 1915:

Daughter, aged 49, of M.D.Lond. who practised in London and India, and died in 1873. Applicant was able to supplement an income of about £20 per annum by teaching French, but owing to ill health is unable to continue this work. Relieved twice, £10. Voted £10 in two instalments.

Widow, aged 51, of M.D.Dub. who was in the R.A.M.C., and died in 1905. Applicant lives in a flat rent free, and has a small army pension. In addition to her four daughters, ages 21 to 26, she has her mother partly dependent on her. None of the daughters are strong, nor have they been trained for work. They have recently been training for nurses. Voted £5 and referred to the Guild.

Daughter, aged 55, of L.R.C.S.Glasg. who practised at Glasgow, and died in 1883. Applicant managed to earn a living before the war by teaching music, but since October, 1914, has practically lost all her pupils. Only permanent income £4 12s. per annum, and lives in own house. Voted £12 in twelve instalments. Recommended by the Glasgow branch of the Guild.

Daughters, ages 44, 50, 55, of M.R.C.S.Eng. who practised at Bodmin and died in 1912. Until father's death they were all able to live comfortably together, as the father had a life interest in some property. Only income of the daughters £5 each per annum. Voted £18 in twelve instalments jointly, and referred to the Guild.

Widow, aged 73, of M.R.C.S.Eng. who practised at Rye and died in 1891. Applicant has cataract in both eyes and unsatisfactory health. Has two daughters, both married. Lives in own house, but has only very limited means. Voted £12 in twelve instalments.

(To be continued.)

¹ BRITISH MEDICAL JOURNAL, March 6th, 1915, p. 429.

MEDICAL CARE OF SCHOOL CHILDREN.

(Continued from p. 66.)

TUBERCULOSIS.

THE chapter on tuberculosis in school children is chiefly noteworthy for the valuable tables giving figures concerning the extent to which tuberculosis is prevalent among children. The first of these tables has been compiled by Dr. T. H. C. Stephenson, superintendent of the Registrar-General's office; it gives the mortality at several ages from all causes and from tuberculous diseases for the last eight years in England and Wales. Death from all causes is high in the first year of life, being nearly ten times as great as that from all causes for the five succeeding years, and thirty times as great as in the second five years. From phthisis the deaths in the first year are as heavy as in the next five years, and nearly twice as heavy as in the second five years of life. In the succeeding five-year groups there is a gradual increase in the death-rate, so that in the group 20 to 25 years it is more than five times as great as in the 1 to 5 year group. Other forms of tuberculosis account for many deaths in the first year of life, the percentage being more than twice that for the succeeding five years; then, for each succeeding five years, there is a steady decrease in the tale.

Returns derived from the examination of school children suggest a slight diminution of the incidence of the disease amongst them. Comparative returns of town and country areas show that the incidence is higher for town areas. There is a solitary exception in the case of Worcestershire; the return of "phthisis" made by this county education authority is higher than that received from any other area, and it is nearly twice as heavy as the next largest on the list. In contrast to this the return for "other forms of tuberculosis" is well within the average. The figures are derived from the examination of 7,128 children, amongst whom 148 cases of phthisis, besides 250 doubtful cases, were reported. Such a return as this is another example of the desirability for some sort of cross-examination by the Board and the presentation of some explanation for the anomalous returns.

MEDICAL TREATMENT.

The report takes a very optimistic view of the progress of medical treatment amongst school children. Many of the most fruitful activities are of the nature of voluntary undertakings on the part of the local education authorities; the initiative in regard to treatment schemes rests with the local authority, and a considerable proportion of the cost is borne by the local taxpayer. The work has hitherto been placed, for the most part, in the hands of the local doctors. The introduction of the systematic examination and treatment of the children has produced a higher standard of health, both children and adults look upon accustomed ailments in a different light, and the desire for something better than the endurable has been fostered.

The war has put a check upon many of the activities of the school medical service, and perhaps in no branch has its effect been more heavy than in the stoppage of schemes of treatment. But it is considered to be "extremely important to maintain the machinery, both of inspection and treatment, in good working order. The need for such organization is likely to prove greater in the future than in the past."

A feature of the year is the great increase of the provision for dental treatment. In London for the year beginning April 1st, 1915, provision has been made for the treatment of 125,486 defects, including 63,140 dental cases. During the year the number of authorities providing treatment has increased from 139 to 179, and the treatment clinics now number upwards of 350. There appears to be a steady growth in the appreciation of the work by the people. Sheffield reports that the proportion of children obtaining treatment for which the education authority make provision has risen from 34 per cent. of the children treated in 1908 to 66 per cent. in 1914. It is satisfactory to note that there is a growing recognition of the view that the treatment of school children found on inspection to be defective is no part of the work of the voluntary charitable hospitals. This was first impressed upon the authorities by the inability of the hospital staffs to cope with a veritable inundation; now the authorities

recognize that half the value of their costly inspection is lost by merely turning over the children to the out-patient departments adapted to the adult population. Children's cases need a systematic following up, both to secure regular attendance and the effective application of the remedies ordered; these desiderata can only be secured through the school authority's own staff or an associated voluntary Care Committee. The organization of treatment is not difficult in town, but it is quite otherwise in the counties; each district has its own particular difficulties to face, and, as no two areas are exactly alike in these respects, each county scheme has to be developed according to local circumstances. Notwithstanding the difficulty, the work is progressing. Out of 62 such authorities (London excluded) treatment of one form or another is now undertaken by 50; it includes treatment of minor ailments, dental defects, ringworm (*x* rays), tonsils and adenoids, defective vision, and the provision of spectacles. The chief difficulty in rural districts appears to be with the staffs. A nurse to be of any good must be on the spot, and there is not sufficient work to keep one school nurse. It is suggested that each of these small areas should have one whole-time nurse to attend to several public health duties—school attendance, school nursing, tuberculosis, and district health visiting. In some places the local medical practitioners work under contract scheme: medical specialists come from the central town of the area; a medical staff is appointed by the local education authority; a school clinic is staffed by the local practitioners, or the local hospital is used. It would appear that each of these methods has its rightful place according to the type of work. Temporary clinics, working in a district over a sufficient period and then being transferred to a quarter where there is more need, have been found valuable. An even more mobile form of clinic, the "travelling clinic," has been worked with great success for dental purposes by caravan; the equipment of one such clinic is carried by the dentist on the back of his motor car.

DENTAL DISEASE AND TREATMENT.

It is noted that there is a steady appreciation in all parts of the country of the necessity for dental treatment. Several doctors have made comparative investigations of the state of the teeth of children of different types. One writes: "On the whole the possession of perfectly sound dentures seems to confer unexpectedly small advantages. Even the apparent advantage in height and weight . . . may be a matter of race rather than of better health." Another found that "in general terms the best nourished children compared distinctly unfavourably as regards their teeth with the children as a whole," and he concludes that "in the aggregate bad teeth is not the cause of malnutrition in children." These conclusions are in conflict with those arrived at after similar investigations by other doctors. A most systematic inquiry was made in Lancashire, and a direct association between bad nutrition and bad teeth was found. Children with "excellent" nutrition had on an average 3.6 decayed teeth per child, with normal nutrition 4.4 bad teeth, with subnormal nutrition 5.2, and with bad nutrition 6.2 decayed teeth. Be the effect of bad teeth immediate or not there is no doubt of the national loss in the end. In the annual report of the Director-General of the Army Medical Service for 1910 it is written that 44.3 per 1,000 recruits were rejected on account of bad teeth. "This high ratio bears eloquent testimony to the poor dental conditions of the classes from which the majority of the recruits are drawn." If the state of the children's teeth be bad it is certain that the same persons when adults will have yet worse teeth, for all the evidence, of which some is given, tends to prove that there is a progressive deterioration in the state of the permanent teeth with every year of school life.

Of predisposing causes the two most important appear to be improper feeding of young children, and excessive sweet eating. Others put alongside these the lack of the toothbrush, and the effects of certain illnesses, such as rickets. But there is general agreement that food is the most potent influence. One illuminative observation comes from Dr. Milligan of Bootle; he has shown that children in the poor schools frequently have the cleanest and soundest teeth. This observation, we have reason to believe, is correct. He adds that "the reason for this is to be found

in the domestic arrangements of the poorer classes, and the fact that the children are left to pursue their natural aptitude for chewing uncooked fruit and vegetables." Of the virtue of the toothbrush there can be no question, but the assertion of one medical officer that "clean teeth do not decay," is unfortunately not of universal application.

The great benefit that may be obtained by short demonstrations given in the schools by the visiting doctors is brought out. These lessons, when well and dramatically given, with a sufficiency of blackboard illustration, arouse keen interest amongst the children, the teachers, and ultimately the parents.

Lengthy tables of figures are given of the incidence of dental defects in different areas, and here again we find the same conflict of testimony as in other figures. One would expect the figures of Cornwall and Torquay to bear some near resemblance, but they are as the poles asunder—Cornwall takes first prize for good teeth, Torquay is nearly last.

Mention is made of the need for experienced anaesthetists for the purpose of general anaesthesia, if and when this is practised. Dr. Norman Bennett lays great stress on this point, as important both from the patient's and the doctor's point of view. "Time is saved and the child benefited." It is worth while to quote one paragraph:

In the administration of nitrous oxide for children it is of cardinal importance to give a certain amount of air or oxygen. In this way struggling is prevented, cyanosis is minimized, and the anaesthesia is prolonged. This point was certainly not generally appreciated. The routine procedure of washing the face-piece after each administration was not carried out. After administration ceased an experienced anaesthetist can greatly assist the dentist by holding the head in a particular way, and by manipulating a Mason gag quickly and correctly when necessary. These points are of more importance with children than with adults, because they easily become more cyanosed, relaxation is often very sudden, and, generally speaking, the physiological changes induced by the anaesthetic are more rapid and less easily controlled.

Point is made that the general anaesthetic should not be given by the operator except in cases of exceptional emergency.

There appears to be considerable difference in the practice adopted at different dental clinics. The figures of the London area show this well: 32,430 children were attended to; taking the children as 1, the number of attendances was 1.5; temporary teeth extracted, 4; permanent teeth, 0.5; stoppings, 1. The extractions and stoppings vary considerably in the constituent clinics; two extremes are: Marylebone—temporary teeth extractions 9, permanent 1.3, stoppings 1; Peckham—temporary 2.8, permanent 0.1, stoppings 2. These would appear to be extreme examples of "radical" and "conservative" dentistry; and if the conservative practice is justified, then the rate of extractions in some places would seem to be excessive.

OPEN-AIR EDUCATION.

The demand for facilities for the open-air education of weakly children has caused many experiments to be made. The cost of special provision has led to the use of the school playgrounds. On this Dr. Hamer, writing of London, says: "The results of the classes appear to show that the average child gains considerable advantage in health and vitality from education upon open-air conditions, such as can be given in a suitable school playground. In connexion with the campaign against tuberculosis there is necessarily arising a demand for the further provision of facilities for open-air education for debilitated children. Although the ordinary playground class does not well suit the needs of the more delicate child of phthisical tendencies, the results of the Hackney Marsh class appears to show that there is room for the development of such children in open spaces and parks." There is a whole world of difference between an open space and the open draughts of a town school playground; the latter is pleasant enough for an occasional class in the summer, but in the winter it is no place for any but the active. Testimony is given to the excellent effects that have been derived from the activities of the boy scouts movement, and the establishment of holiday schools and camps.

THE CRIPPLES.

The incidence of physical deformity and the causes thereof are shown in several tables. Tuberculosis always

heads the list; it accounts for about 40 per cent. of the cases. Next comes infantile paralysis with about 25 per cent., and rickets with 10 per cent. The remaining 25 per cent. are due to a variety of conditions ranging from accident to congenital deformity. There are now sixty-one special schools with accommodation for 5,005 children. A speciality of the education is to be found in the trade instruction given in the schools for elder children. Girls are taught fine needlework and dressmaking, the boys cabinet making, carpentry, and toy making. The work done by some of these schools is well worth examination.

A special investigation was made in London into the mental condition of the cripple children. The result was a complete overthrow of the popular idea that the cripple was of superior mental development. Amongst 1,080 children not more than 8.5 per cent. were up to the proper standard, and of the remainder who were below normal, 21 per cent. were of exceptionally low ability. A critical review of the cases of children suffering from paralysis shows that the mental development was inversely proportional to the height of the lesion. In poliomyelitis 48 per cent. were average children mentally, in hemiplegia 32 per cent., and in diplegia and paraplegia only 10 per cent. Excellent work is done by the after-care committees in the supervision of these children; every effort is made to associate them with societies, clubs, and other friendly associations, with a view to continuing educational influences and preventing degeneration. This section closes with an important paragraph headed

The Training of the Cripple Soldier.

It is hoped that the experience gained by some authorities in fifteen years' administration of cripple schools may be of timely use in helping to provide for cripple soldiers. Their numbers will be large; they will in many cases be unable to follow their old trades; they will have to be taught a new means of earning a livelihood, and their claim for consideration will be pressing. Many are already returning home, and no time is to be lost if they are to be saved from a condition of lifelong inactivity and poverty. The work already organized by Mr. C. Arthur Pearson for blinded soldiers at St. Dunstan's, Regent's Park, will serve to show what can be done in a short time: 50 soldiers are now receiving instruction in new trades; workshops are being erected and residential accommodation being provided for 120 men. They are being taught carpentry, boat repairing, mat making, basketry, and poultry farming, bee keeping, market gardening, and massage. Special attention is given to recreation, including rowing and swimming. A similar effort, though unhappily on a much more extensive scale, is required for cripple soldiers. In order to make appropriate provision in particular areas or in suitable circumstances four steps may be taken as follows:

1. A complete register of cripple soldiers should be formed, suitably subdivided into those who are trainable and those who are not.

2. Local education or other committees should co-operate with the military authorities on the one hand and ameliorative agencies on the other with a view to organizing a scheme of training.

3. Day and residential technical classes should be established, and the subjects should include carpentry, cabinet making, toy making, tailoring, boot making, horticulture, etc. Provision should also be made for the apprenticeship of students to craft trades of higher type—watchmaking, engraving, working in precious metals, etc.

4. After-care supervision would be necessary, and in many large towns considerable experience has now been gained in the work.

Schools for the instruction of cripples, if established by local education authorities, can be recognized for grants under the Board's regulations for technical schools. The Board is therefore in a position to assist movements of this nature, not merely in advising as to the scope and nature of schemes of instruction, but by affording financial aid.

The report contains also sections dealing with physical training, provision of meals, and the employment of children, but no new facts arise for remark. Among appendices, the most important appears to be that dealing with the physical defects of leavers in industrial areas, in residential towns, and in rural areas.

In the autumn of 1915 the incidence of diphtheria in Berlin assumed alarming proportions, and in the eight weeks August 1st to September 25th 1,276 cases were notified, as compared with 907 in the same period of 1914. The deaths from diphtheria in these eight weeks of 1915 numbered 111, as compared with 74 deaths in the same period of 1914. The authorities in Berlin increased the staff of nurses, and steps were taken to provide anti-toxin free of charge.

British Medical Journal.

SATURDAY, JANUARY 16TH, 1916.

THE CAMPAIGN IN EAST AFRICA.

It seems clear that a campaign of considerable importance is commencing in East Africa. Like all campaigns in tropical countries, its success will, in large measure, depend on the efficiency of the means adopted to prevent the occurrence of disease among the troops engaged.

When large bodies of men, natives of a temperate climate, are brought into a tropical country, they are exposed both to the diseases which they may carry with them from their homes and to diseases indigenous in the country to which they come. Troops brought to German East Africa from South Africa or elsewhere may therefore suffer both from the ordinary diseases of their native countries and from those tropical diseases which exist in East Africa; the fatigue and exposure inseparable from military operations will add greatly to their susceptibility. Owing to these two causes the problems presented to the military medical officers by the East African campaign will be especially difficult of solution, and success will, to a great extent, depend upon the loyal co-operation of the troops, and upon the observance by all ranks of the preventive and curative measures advised by the medical authorities.

German East Africa covers so large an area that local conditions vary greatly in its different parts and with the season of the year. But while it is on this account not possible to go into details, some of the special difficulties which will be met with during the East African campaign can be described and the methods by which they may be successfully countered stated in a general way.

There will probably be little difficulty in controlling the diseases which the troops bring with them, though it must not be forgotten that sometimes in East Africa it may be cold enough to make pneumonia, and other diseases often precipitated by exposure, a real danger. Minor tropical diseases, such as various indeterminate fevers of short duration, are certain to be a source of discomfort, and it has to be remembered that there are centres in East Africa where plague is endemic; but these will probably be avoided.

The four diseases which might very seriously interfere with the success of the East African Expeditionary Force are tick fever, malaria, dysentery, and—especially if it is necessary to use animal transport to any great extent—trypanosomiasis.

Tick fever occurs everywhere along the Central African trade routes. The disease is caused by a spirochaete, which is carried from man to man by the bites of a tick, though it may also be transmitted by lice. The fever develops soon after the infecting bite. It is a relapsing fever, consisting of three or more attacks, each of three or four days' duration, recurring at intervals of about a week. If untreated, the disease will incapacitate a man for about five weeks, more or less. If those infected are quickly treated by the injection of salvarsan and properly nursed, recovery is prompt and the mortality very small. If, on the other hand, there is a lack of proper

treatment and nursing, the mortality may be high. The tick—called in Swahili *Kimputu*—is found wherever Swahili traders have gone. In its habits it is much like a bed-bug, and is certain to be found in every native house, new, old, or deserted, along the trade routes. Natives living in districts where ticks exist will often deny their presence or insist that a tick bite has no ill effects. Such persons have become immune to the fever; newcomers, who sleep in houses where ticks exist, are almost certain to be bitten and to be attacked by the fever. There are on record many instances in which caravans coming from a tick-free to a tick-infested district have been stopped because every individual comprising them had contracted tick fever. Since the ticks only exist in native houses, and especially along established trade routes, they may be avoided by sleeping always in camps instead of in native towns and by avoiding old camping places on trade routes.

Means should be, and no doubt will be, taken to impress on every soldier engaged that malaria is caused by a parasite transmitted from man to man by a mosquito. When once this fact is firmly fixed in the minds of soldiers the necessity for mosquito nets will become apparent to them, and they will also be able to understand the need for the careful control of those who have chronic malaria and for the prophylactic use of quinine. French and Belgian native soldiers have for many years shown that it is possible for a soldier to use a mosquito net; they count as one of their most necessary possessions a box-like mosquito net which weighs perhaps half a pound and measures about 3 by 3 by 6 ft. when open. It is supported by strings from the top and has no side opening. These nets are made of mosquito netting when it can be obtained, but more often than not of common white cotton cloth, "Americani." If our troops employed such nets, and if each man took daily with his dinner from 3 to 5 grains of quinine, much would have been done towards lessening the number of men who will be invalidated on account of malaria. Another point of personal hygiene is to wear knee-breeches, or better, baggy knickerbockers, and not shorts which leave the knees bare; shorts seem very popular among our men in warm climates, but they expose an unnecessarily large area to the attentions of the mosquito, the tsetse, and the tick. An administrative point which ought to be constantly before the minds of officers, including those on detachment duty, is that native children very commonly harbour the malarial parasite; the proportion varies, but is usually very high, even among those children who appear to be in good health. The fact affords an additional reason for avoiding native villages and camping in the open beyond the range of the excursions of the small child.

Bacillary and amoebic dysentery both occur in East Africa, and are contracted by the ingestion of contaminated water or food. Water is an especially common source of infection, but all ranks should be urged not only rigorously to abstain from drinking water that has not been boiled or sterilized otherwise, but also from eating uncooked food. The flat taste of boiled water, at first disagreeable, is no longer noticed after it has been used for a week. Circumstances may make it impossible for drinking water always to be sterilized by heat, and in such an event chlorination might be substituted.

The trypanosomes of "sleeping sickness" and "tsetse fly disease," popular names applied to trypanosomiasis affecting men and animals respectively, are transmitted from animal to animal, or from man to man usually by the bites of a tsetse fly, but some-

times by other biting flies. Unfortunately, there is no uniformly successful treatment for these diseases. As there is no drug by which they can be controlled, it is doubly important that the bites of flies should be avoided. It is often possible to do so by keeping away from the neighbourhood of streams and areas where the flies are known to occur.

Tropical medicine has attracted many students during the past few years, and it is certain that there will be no lack in the field of medical officers who have both a practical and theoretical knowledge of tropical diseases. The great advantages which might be derived from the establishment, at some convenient point or points, of well-equipped laboratories are very apparent. Such laboratories would be of the utmost value not only for diagnostic but for remedial purposes.

A successful outcome to the application of the measures the military medical service will advise for safeguarding the health of an unusually large military expedition in a tropical country will be eagerly expected. In order that this fortunate result should be attained it seems essential that men as well as officers should understand something of the reasons for the precautions recommended. A brief printed statement about mosquitos and malaria, ticks and the fever they cause, about dysentery and trypanosomiasis, would enable them to understand the instructions concerning the use of mosquito nets and the proper employment of a water-bottle, and prepare their minds to benefit from the talks and admonitions that medical officers serving in East Africa will, without doubt, give to the men of the commands with which they are serving.

EDUCATION TO-DAY AND TO-MORROW.

LAST week a number of societies concerned with education, and consisting for the most part of associations of schoolmasters and schoolmistresses, met in London; they were linked by a conference of educational associations, opened on Monday, January 3rd, in the Great Hall of the University of London by the Vice-Chancellor, Sir Alfred Pearce Gould. An inaugural address was delivered by the Principal of the University of Birmingham. He spoke on education after the war, and this subject, and that of education during the war, were the chief topics discussed at all the meetings. Sir Oliver Lodge said that the educational danger of Germany had been disclosed by its conduct of the war; it was the heavy pedagogic grind, the desperate worship of material good, the soulless preparation for business, and the concentration of a purely material idea. The old sentimental Germany with a message to the soul of the human race had been slain, and a ruthless monster had taken its place. The dangers in this country were, he thought, the neglect of intellectual things and concentration on physical prowess and a passive kind of material prosperity; the satisfaction with book knowledge; and widespread indifference to natural facts not only among the general public but among the leaders, leading to contempt for investigation and expert knowledge. Canon Masterman, in addressing the Teachers' Guild of Great Britain and Ireland, took up the same parable. The Prussian leaders of Germany after 1870, he said, had extended the claim of the State over the bodies of its citizens to their minds, and even, in Bismarck's *Kulturkampf*, to their souls. Education had shown itself capable in unscrupulous hands of producing one of the most colossal catastrophes in history. Our fault in this country, on the other hand, was the lack of a clear

idea of the object of education; consequently, the results were not proportionate to the cost and effort they involved.

Very little was said at any of the meetings about the teaching of Greek and Latin, but a great deal about the need for proper instruction in modern languages, and also for giving better opportunities for becoming acquainted with the modern literature of foreign nations.

When we come to look into matters of detail we are attracted by a very outspoken address by the Professor of Applied Mathematics in the Imperial College of Science, and some rather revolutionary proposals with regard to medical education by the Regius Professor of Medicine at Oxford. Professor Whitehead, in pleading for a reform in the aims of education, said that the devil in the scholastic world of this country had assumed the form of a general education consisting of scraps of a large number of disconnected subjects, and with the artfulness of the serpent had entrenched himself in the ditch of the matriculation of the University of London, with a wire entanglement formed by the Oxford and Cambridge schools examination. English education, he asserted, was suffering from a lack of definite aim: we had not made up our minds whether to produce amateurs or experts, but he insisted that it was impeded also by external machinery which killed its vitality. His conclusion was that the results of education in the schools should be tested not by rigid examinations of the pupils, but by proper inspection and correction of the schools, while leaving each a unit with its curriculum based on its own needs.

Sir William Osler, in addressing the public schools science masters, pleaded that boys designed for the medical profession should leave their hands fit to begin their special studies. He urged that earlier and more extensive work in science subjects would save time at the universities. He ventured on the assertion that by the time a boy was 16 he had already, in the majority of instances, selected his career, and from that proposition deduced the conclusion that the sixteenth and seventeenth years should be devoted to the preliminary sciences—physics, chemistry, and biology. A boy would then be fit to go to the university at 18 and to proceed at once with physiological chemistry, physiology, and anatomy. He contended, therefore, that the school problem was to organize teaching so as to have a continuous science course through two years, and for this teachers, laboratories, and a systematic organization of the courses were necessary. The teaching in chemistry at the schools was not yet good enough, but if it were improved in this and the other preliminary sciences he believed that by shortening the vacations and rearranging methods of instruction it would be possible to return to a four years' curriculum for medical students. The average man would then qualify at the age of 22, spend a year in hospital or in post-graduate study, and start in life at 23. Sir William Osler argued that at present valuable time was being lost and much needed money wasted because science was a Cinderella in the kitchen instead of being the dominant partner in the educational family.

Sir William Osler's picture of the possibilities of the future is very different from that drawn in the reports to the General Medical Council of the actual state of things in the recent past. From a report made by the Education Committee, after a very full investigation of the curriculum of 1,111 who qualified in 1906, it appeared that the mean length of the curriculum in the United Kingdom was seven years (6 years 11.3 months). In England it was seven and a half

years, and in Scotland and Ireland a little over six and a half years. One result was that the mean age of qualification was in England 26 years and in Scotland and Ireland 25 years. This is with a minimum curriculum of five years. The report, it is true, was prepared nine years ago, but there is no reason to suppose that there has been since then any important alteration.

We are not quite sure whether Sir William Osler means to suggest that the minimum curriculum should be reduced to four years, or whether, if so, it would have any such effect in reducing the average age of qualification, as he supposes. Already teachers at all schools are complaining that it is impossible to crowd into the five years all the subjects which a student ought to learn, and it might be that the reduction of the length of the curriculum would only have the effect of increasing the number of rejections at examinations. But we take it that he would advise any reduction only if his other proposals with regard to the improvement of scientific education at schools and early differentiation of boys at schools were also accepted. We are disposed to think that the cry about the shortage of doctors at the present time has been exaggerated, and have seen no conclusive argument that there will be any shortage after the war. We may, perhaps, take warning by the example of Germany. At the beginning of the war the Government of that country relaxed the regulations and permitted a large number of senior students to obtain a licence to practise after examinations taken at an earlier date and under less stringent conditions than prevailed before the war. This policy has been strongly condemned by the medical profession in Germany. We are far more disposed to agree with Mr. Runciman, who in a very admirable speech in the debate in the House of Commons on January 10th laid it down that one of the first necessities of this country, if she wishes to hold her own during the time of war and when the war is over, is to improve research methods, the education of the people, and the training of young men. He repudiated the suggestion that we should attempt to economize on the money now spent on colleges and modern appliances. "There are," he said, "other directions in which we can cut down expenditure with less rational damage."

It is, we submit, something of a disgrace to our great public schools and to the universities of Oxford and Cambridge that a man, after passing through those venerable institutions with the highest distinction, may be totally ignorant, and will not be ashamed to admit that he is totally ignorant, of the elements of science—ignorant not only of the facts, but of the methods of science, and void of the intellectual training which it affords.

THE ARMY COUNCIL AND MEDICAL RECRUITING.

The following official communication has been issued by the War Office (January 12th, 1916):

"The Army Council consider that no qualified medical practitioner who is willing to accept (if offered) a Commission in the Royal Army Medical Corps should be accepted as an ordinary combatant.

"It is understood that the Central Medical War Committee will circularize the profession, stating that any medical practitioner who has enlisted under the group system should immediately enrol himself under the Committee's scheme as willing to accept a Commission in the Royal Army Medical Corps, if offered him.

"To every practitioner who enrolls the Committee issues a Certificate of Enrolment.

"Every medical practitioner who has attested and enrolled under the Central Medical War Committee's scheme should, when called up, produce to the recruiting officer his Certificate of Enrolment. He will then not be posted to a combatant unit, and will await instructions from the Central Medical War Committee."

The draft of the circular letter referred to above was considered by the Central Medical War Committee at its meeting on January 12th, and will be issued immediately.

WELFARE OF MUNITION WORKERS.

The Health of Munition Workers Committee has presented a memorandum to the Minister on the need of careful supervision of the welfare of munition workers. Attention is drawn to the deficient housing accommodation in certain districts and to difficulties of transit when no local accommodation at all can be obtained; to the need for the provision of adequate and appetizing meals at the works, and generally to the subject of the means which should be taken to prevent mental strain produced by long or exceptional exertion. The problem concerns at least three classes—adult men, boys, and women. In some munition works steps have already been taken to extend the movement in this direction started before the war. In 1913 a conference of thirty representatives of welfare workers at a number of factories was held at York. Since then the number of such workers has largely increased. At one of the largest of the munition factories a chaplain, who before taking orders served several years in a large engineering firm, has been appointed to adjust difficulties in the families living in the hostels, to look after the children, and to organize healthy recreation, both indoor and outdoor; a doctor has been appointed, and an infirmary, with a small operating theatre, has been taken over for cases removed from the hostels. At another factory the supervisor looks after safety appliances and organizes first aid stations and canteen accommodation. In the case of another munition firm a shop committee has been made the intermediary for dealing with various questions affecting the detailed management of the workshops and the institutions for the benefit or pleasure of the men, such as dining arrangements and rifle clubs. Women supervisors, where the need for them was felt, have been most successful, for it has been found that the presence of a capable woman, of broad sympathies, has provided the best and quickest aid to the solution of many of the problems affecting women's labour. Her duties include such matters as the provision and maintenance of sufficient sanitary accommodation, and general supervision of the woman's health to see that she is capable of withstanding the physical strain and stress of work, and to endure long hours, overtime, or nightwork. It is recommended that a woman of good standing and education, experience, and sympathy should be selected for such work; she should live near the factory, and in "national" factories should be appointed and paid by the Ministry of Munitions, in "controlled" establishments by the employer, but her appointment should be reported to the Ministry. It is pointed out that courses of social study designed for students preparing themselves as members of various local authorities and as welfare workers in factories have been established in the universities of London, Birmingham, Manchester, Leeds, Bristol, Edinburgh, and Glasgow.

WELCH'S BACILLUS.

In a recent elaborate study of the *Bacillus welchii* Dr. J. P. Simonds¹ gives a clear, though necessarily inconclusive, account of a group of microbes that has

¹ Monographs of the Rockefeller Institute for Medical Research. No. 6. September 27th, 1915. New York. (S. roy. 8vo, pp. 130. \$2.00.)

occupied the attention of pathologists and bacteriologists for many years. The bacillus of Welch was first fully described by Welch and Nuttall in 1892; Dr. Simonds has collected from the literature no fewer than 476 references to papers and books dealing with it and its congeners. Welch's bacillus is one of a group of bacteria the members of which defy satisfactory classification. Welch and Nuttall named their organism *B. aerogenes capsulatus*; identical or closely related bacterial species have received eight or ten other names, and include Achalmé's bacillus alleged to be the cause of acute articular rheumatism, Klein's *B. enteritidis sporogenes*, Veillon and Zuber's *B. perfringens*, Fraenkel's *B. phlegmonis emphysematosae*, and many other varieties of "gas bacillus" generally. The literature abounds in contradictory statements as to the biological characteristics of these bacilli, and it may be added that these characteristics are liable to considerable changes in accordance with the methods of culture or subculture employed. Speaking generally, however, the bacteria are large, anthrax-like, Gram-positive, non-motile, strict anaerobes; they form spores in alkaline media, and bring about the stormy fermentation of milk—coagulation takes place quickly, and the clot is broken up by the abundant formation of gas. After an elaborate consideration of their cultural characteristics, Dr. Simonds proposes to divide the bacteria of this group into four subgroups, on the basis of their ability to produce acid and gas or to sporulate in media containing inulin and glycerin. He notes the great variability among members of the group in the formation of toxins and haemolysins and in pathogenicity to both animals and man. In man either local or general infections of the most various tissues and organs of the body by these microbes have been recorded; gas formation is habitually observed, and in many cases leads to the production of "foamy" organs or emphysematous gangrene, a condition that has unfortunately received abundant illustration among the wounded in the present war. Some years ago Herter endeavoured to show a connexion between pernicious anaemia and the presence of excess of *B. welchii* in the stools of the patients; the connexion of the bacillus with epidemic or sporadic diarrhoea in either children or adults is much more definite, and is discussed by Dr. Simonds at full length. The bacillus is undoubtedly a normal inhabitant of the intestines of adults, and is sometimes found in small numbers in the stools of infants; if the bacilli are present in excessive numbers, and if the diet contains an undue proportion of fermentable carbohydrate, diarrhoea with highly acid stools is likely to result. Dr. Simonds claims that the number of spores of *B. welchii* in the stools, estimated by a technique which he describes, is a reasonably accurate index of the number of actively fermenting, disease-producing organisms of this type higher up in the intestine. The acid they produce is butyric acid, and this is a highly irritating substance. The condition may be cured by substituting a diet rich in protein for one rich in carbohydrate, and by giving butter-milk which encourages the growth of bacteria producing lactic acid at the expense of those producing butyric acid.

THE MEDICAL TOPOGRAPHY OF PERSIA IN 1873.

In view of our present military commitments in Persia and the valley of the Euphrates, it is not without interest to read an account of the climate and prevalent diseases of that district as they were recorded by an officer of the Army Medical Department—Surgeon-General J. H. Evatt, C.B.—in 1873,¹ in the course of a tour of inspection up the Persian Gulf and on to Bagdad. The possible importance of such a route from Europe and Asia to India was the motive of the journey, and such notes were taken as might prove useful to an officer of the Army Medical Department engaged in service there or thereabouts. From the point of view of health and sanitation the

report is depressing. Of Bushire, the chief town near the head of the Persian Gulf, it is said that "Remittent fever of a bad type is common. Dysentery is common. Cholera rages from time to time. Ophthalmia is common." Of Basra we read that the town and neighbourhood are "decimated by malarious diseases, such as ague and remittent fever. . . . Every man in Bassorah has ague. . . . Cholera has several times attacked the place. . . . The Bagdad or Aleppo boil has marked many people here." Higher up country, at Kurna, where the waters of the Tigris and Euphrates join, the traveller in 1873 had at least the felicity of viewing the Garden of Eden, although it was not even then at its best. We are told that "to-day the happy garden is the post of some Turkish soldiers; around the base of the reputed tree of knowledge, which is still shown to travellers, useful vegetables grow, and high up above the garden I noticed in mid-air the telegraph wire. . . ." But at the present time the Garden of Eden is no longer to be found at Kurna, if Sir William Willcocks is to be believed, but much further off, in Mesopotamia. Between Kurna and Bagdad lay 350 miles of desert crying out for irrigation and cultivation in 1873 as at the present time. Bagdad in 1873 had a population of nearly 100,000, and was full of disease; in 1832 it lost 60,000 of its 150,000 inhabitants by plague, and forty years later had still not recovered from the shock. Cholera, Bagdad boil, fevers of remittent and low type, and small-pox are mentioned as the chief medical scourges. "The hospital accommodation for the civil population is almost nil. There is a municipal physician, an Englishman, but he has no medicines. . . ." It is observed that the civil hospital had been annexed temporarily by the Turkish Viceroy for the military, and was an excellently appointed institution. It is particularly interesting to note that the writer of this report considered the construction of a railway down the Euphrates valley, as an alternative to the road through Egypt, ridiculous from the British point of view, adding, "Indeed, no other nation wants this line but England." Subsequent history has not confirmed this view of the matter; but the writer's final conclusion may be quoted with the most complete approval: "The simplest way to keep the road to India open is by being strong in Egypt, and such we can any day be."

THE FULL DIET FOR ENTERIC FEVER IN CHILDREN.

Dr. H. D. CHAPIN remarks¹ that in New York, at any rate, enteric fever occurs at least as freely among children under 14 years of age as it does among adults. Thus, in an epidemic occurring towards the end of 1913, of 521 cases, 36 were under 5 years old, 98 were aged 5 to 9, and 87 were aged 10 to 14—in other words, over 42 per cent. were 14 years old or less. The epidemic was traced to infected milk; 70 per cent. of the cases reported were getting milk from one dairy. When the milk from this source of supply was cut off by the New York Health Department the epidemic ceased. Dr. Chapin treated 11 children, aged from 2 to 8, during the epidemic. All recovered, and all gave a positive Widal reaction; none showed any rose spots or enlargement of the spleen. The blood counts taken showed little diminution in the red cells and no leucopenia except in one instance; a differential count of the white cells, which averaged 8,300 per c.c.m., showed a relative increase of the polymorphonuclears at the expense of the lymphocytes. The gastro-intestinal symptoms were not marked; the children all received the general ward diet with the exception of meat; the attempt to make them take food to the heat-value of 40 calories per kilo of body weight was not successful while the fever lasted, which was for twenty-two days on the average. No severe complications and no relapses were recorded. It is of interest to note that the diagnoses made before the

¹ Army Medical Report for 1874, vol. xvi.

¹ Transactions of the American Paediatric Society, 1915, xxi, 51.

admission of these patients were very various. Enteric fever was diagnosed in 5, and no diagnosis was made in 2; in the remaining 4, meningitis, miliary tuberculosis, bronchitis, and Brill's disease (an aberrant type of typhus fever, in all probability) had been diagnosed. The value of a diet of high heat value in the case of children with enteric fever is further elaborated by Drs. L. E. La F  tra and L. C. Schroeder,² who have treated 48 cases, aged from 1 to 12, on these lines. Dr. A. I. Kendall³ had given good physiological and bacteriological reasons for supplying enteric patients with a full diet rich in carbohydrates; and Coleman, in an account of his experience with 111 cases, had found that an increased amount of fat in the dietary did not tend to cause diarrhoea. Drs. La F  tra and Schroeder's patients were treated on the usual lines, being sponged if the temperature reached 103.5   F., and being kept in bed on balconies or in rooms with open windows. Seven patients received vaccine treatment, which had no perceptible influence on the course of the disease. All 48 but one recovered; the death was due to pneumonia. It is noted that the general condition of the patients was remarkably good; the average stay in hospital was four weeks, varying from two to eleven. Abdominal distension was present in six instances, and was troublesome in only one; five patients had blood in the stools. In two cases the loss of blood was serious, and one patient, aged 11, was thrice transfused with 160, 260, and 280 c.cm. paternal blood by the Lindemann method, and also had saline solution intravenously twice and two injections of horse serum. He lost the greatest amount of weight, but during convalescence made up for this by taking a diet equivalent to 8,000 calories a day, or 310 calories per kilogram. In thirty-seven days he increased in weight from 45 lb. to 72 lb. A full account and analysis of the diet in these cases is given; the number of calories actually taken after the first few days varied from 100 to 300 per kilo. Unless toxic nervous symptoms were present, high fever did not prevent the children from taking a generous diet. The diagnosis was established, in 47 of the cases, by a positive Widal reaction in 44 and a positive blood culture in 36. During the course of the fever 29 patients gained in weight, and all but 4 were heavier on leaving the hospital than on entering it. As for the diet itself, the children were fed every three hours from 6 a.m. to 9 p.m. The food was such as would be taken by a child in health, with the exception that chicken cream was the only meat used; eggs and toast were offered from the beginning; lactose, cocoa, and cream were added to milk, which was practically the only liquid food. Among the other solids were bread, biscuits, potato, custard, apple sauce, cereals, and the like. For example, a child of 5 on the ninth day of the disease, with a temperature of 100   F. to 103   F., was taking a diet of 2,430 calories value, containing a pint of milk, half a pint of cream, 17 oz. cocoa at one meal, 3 eggs, 3 slices of bread, and 2 oz. milk sugar. It is noted that the tact and encouragement of the nurses were of great assistance in getting these large diets consumed. The conclusion is reached that the high calorie diet prevents the emaciation customary in enteric fever, greatly increases the comfort of the patients, prevents the occurrence of severe nervous symptoms (which are attributed to the tox  mia of starvation), and lessens the dangers of the disease and its complications.

ACTINOMYCOSIS AND ACTINOBACILLOSIS IN OXEN.

ACTINOMYCES, or the ray fungus, discovered by Bollinger in 1877, is well known to bacteriologists and pathologists as the most important organism of the streptothrix group, and it is recognized that there are at least two different forms of the ray fungus—*Actinomyces bovis* and *Streptothrix israeli*. The actinobacillus, first described

by Lign  res and Spitz in 1902, is a distinct organism, but produces in cattle various forms of disease clinically indistinguishable from those due to infection with the ray fungus. Epizootics of what is commonly called actinomycosis, but due some to the one and some to the other, have been of common occurrence in the herds of cattle in the Argentine and elsewhere. The Local Government Board has published a report¹ by Dr. F. Griffith, who mentions that out of 85,455 imported ox tongues examined by inspectors of foods in the city and port of London between August and October, 1913, no fewer than 4,949 were found to be infected with actinomycosis, chiefly in the glands. In order to determine the exact nature of the organism causing this bovine actinomycosis, or, to use the more comprehensive name suggested by Lign  res and Spitz, actinophytosis, Dr. Griffith has examined 44 specimens taken from oxen slaughtered in this country, 45 Argentine tongues, 2 tongues from North America, and 2 frozen tongues from Siberia. The tongue itself was infected in one Argentine and the two North American cases, showing scattered fibrous nodules up to a centimetre in diameter, and containing gritty or gunny granules consisting of Gram-negative, radiating clubs, and finely granular debris. In all the other cases the tongue itself was not infected, but cascating glands surrounded by fibrous tissue and containing granulation tissue or semipurulent matter with masses of more or less Gram-negative radiating clubs were found attached to it. No definite success attended numerous attempts to grow the causal organism infecting these imported tongues and their glands; inoculation experiments also proved failures. Investigation of the 44 British cases yielded Dr. Griffith rather different and more satisfactory results, given in detail in the report. In 40 instances the infecting organism showed Gram-negative granules and clubs, and pure cultures of it were obtained in 23 cases; all 23 gave identical Gram-negative specimens of the actinobacillus, and a culture, inoculated into a calf, produced a local lesion with the characters of a natural actinomycotic lesion. The histological features and the anatomical distribution of the disease in these 40 specimens were identical with those of the Argentine actinobacillosis described by Lign  res and Spitz, and with those of the 49 imported specimens already described. The remaining four British cases Dr. Griffith puts into a class by themselves; the lesions were situated in each case in the inferior maxilla, and the specific granules formed by the infecting organism were composed of clubs and Gram-positive organisms, including branching filaments, chains of coccil bodies, and short bacilli. Dr. Griffith reaches the general conclusion that actinobacillosis is widespread in the world, and forms a considerable proportion of the cases of disease in oxen known as actinomycosis.

X-RAY INTENSIFYING SCREENS.

So many radiographers are now using intensifying screens to accelerate x-ray exposures that one little practical point, brought out in the course of a discussion on the subject at a recent meeting of the R  ntgen Society, may be worthy of note. It is that, if an intensifying screen is used, there is no need to employ a special x-ray plate, and some speakers even claimed that the results when the x-ray plate was not used were quite distinctly better. Care should be taken, however, to choose a plate which is specially sensitive to the blue-violet light of the screen. The trouble with these intensifying screens seems to be that, while they will give contrast, they blur the very fine detail; and therefore, in chest work, for example, if the instrumentation is such that a full and rapid exposure can be obtained without them, this course is to be

¹ Ibid., p. 67.

² Boston Medical and Surgical Journal, 1913, clxviii, 825.

¹ Reports to the Local Government Board on Public Health and Medical Subjects. New series, No. 107: A Preliminary Report on the Pathology of Bovine Actinomycosis. Food Reports, No. 23. London: J. Truscott and Son, Ltd., 1915. (Price 2d.)

preferred. In the case of ordinary x-ray action the radiation goes right through the grains in the body of the photographic film, but when an intensifying screen is added the action is more like that of light, and the two things work one against the other. Thus the screen cannot increase, and must to some extent destroy, the rendering of fine detail. If a screen is used, the best results are obtained with about one-tenth of the normal exposure, and the tube should be slightly softer for a given subject than would be used if the exposure were made without the screen. Great care should be taken to avoid finger-marks on the screen, which should be dusted with a fine camel-hair brush. The after-phosphorescence of the screen is an important point; this may persist for a few seconds or for as long as twenty-four hours. After-phosphorescence for a few seconds is useful, because to a certain degree it increases the rapidity of the exposure; but beyond this it is a disadvantage, because it upsets subsequent exposures, and the ideal would be never to use the same intensifying screen again the same morning or afternoon.

THE ALLEGED INCREASE OF INSANITY.

DR. SYDNEY COUPLAND, who is a skilled statistician, examines the question of the alleged increase of insanity in his recently published *Harveian Oration*. He shows that the number of insane persons known to the authorities has been continually increasing, out of proportion to the increase of population, for the last fifty-five years. A great part of this increase is due to three causes: first, that a far larger proportion of the insane has become known to the central authorities; secondly, that the death-rate has continually diminished, thus allowing of a larger accumulation; and thirdly, that the recovery-rate also has diminished, with a similar result. The only sound criterion for determining whether or not there is a real increase of lunacy is, he shows, that based upon the numbers admitted to care who are attacked for the first time. It appears—and the admission is rather surprising—that the proportion of first attacks to total admissions has been observed only since 1907. During these eight years the total number of the insane in institutions per 10,000 of the population has steadily increased from 28.25 to 30.19, while in the same time the number of those who were admitted for a first attack has increased, but not steadily, from 4.12 to 4.26 per 10,000 of the population. From these figures Dr. Coupland draws the conclusion that the ratio of first attacks to the population has remained fairly constant, at about 4 per 10,000, while the proportion borne by the total number under care has risen from 28 to 30 per 10,000. This is one way of putting it, but there is another not quite so comforting. The increase from 28.25 to 30.19 is an increase of 6.868 per cent.; the increase from 4.12 to 4.26 is an increase of 3.374 per cent.; so that actually the proportion of first attacks to the population has been increasing nearly half as fast as the proportion of the total number of the insane. This is not quite as comforting as Dr. Coupland's assurance, nor is there much comfort to be extracted from his admission that part of the increase of the accumulation is due to a diminished recovery-rate. The only hope that our present knowledge of insanity permits us to entertain of appreciably diminishing the number of "first attacks" lies in diminishing habitual and long enduring drunkenness and in diminishing the incidence of syphilis.

THE BIRTH-RATE IN WAR TIME.

In a note published in the *BRITISH MEDICAL JOURNAL* of December 25th last year, p. 935, comment was made upon the apparent increase in the birth-rate of males during the last few months. Further light is shed upon this obscure subject in a paper published recently by Dr. R. J. Ewart,¹ dealing with the influence of the age of

the grandparent at the birth of the parent on the number of children born and their sex. As a result of a minute statistical inquiry, Dr. Ewart concludes that the pre-natal mortality has an important effect on the production of variations of the sex-ratio at birth in any community. Prenatal mortality affects males more than females, and is closely connected with infant mortality, which is itself higher in the case of elderly parturients. How far these considerations would explain the predominance of male over female births alleged by "F." and Dr. Peck in the note referred to above is an interesting question that could be solved only by painstaking statistical investigations.

In the list of New Year honours published last week the name of Dr. A. W. J. MacFadden, Chief Inspector of Foods, Local Government Board, was accidentally omitted. He has been appointed a Companion of the Bath in recognition of services during the war.

From a statement issued by the President of the General Medical Council it appears that the number of medical practitioners whose names were added to the *Medical Register* in 1915 was 1,526. This included 269 practitioners with colonial and foreign qualifications. The annual average number added during the five years 1910-14 was 1,172. The number of medical students registered in 1915 was 1,918. The annual average during the five years 1910-14 was 1,441.

Medical Notes in Parliament.

War.

Battle of Loos.—In reply to Mr. Pringle, who asked for official figures of the casualties in the battle of Loos, Mr. Tennant said that it was not possible to define with geographical exactitude the area within which the operations that had been called the battle of Loos took place, nor to divide the casualties occurring in them with precision from those arising from simultaneous operations on other adjacent parts of the front. The figures for the period from September 25th to October 8th, 1915, for all the fighting on the Western front were:

	Officers.		Other Ranks.	
Killed...	...	773	...	10,345
Wounded	...	1,288	...	38,095
Missing	...	317	...	8,848
Total	2,378	...	57,288
59,666				

These figures included the returns from the regular Army and Territorial Force, the Overseas contingents, and the Indian native forces.

Military Hospitals and Asylums.—In reply to Mr. King, Mr. Brace (Under Secretary, Home Department) said on January 5th that ten asylums in England and Wales and isolated parts of two others had been placed at the disposal of the War Office for use as hospitals, and accommodation had thereby been provided for over 14,000 sick and wounded soldiers. Arrangements were in contemplation for converting into hospitals two more asylums. In addition an asylum which at the outbreak of war was nearly completed but not yet occupied was taken over by the War Office, and a similar course would be adopted with another new asylum now approaching completion. Nearly all the civilian patients displaced by these arrangements had been distributed over the remaining asylums, with the result that most of these asylums had at present more inmates than would be considered advisable by the Board of Control in normal times. Every effort was being made to minimize the inconveniences of the arrangement, which was only justified by the exceptional circumstances of the present time.

Antityphoid Inoculation.—Mr. W. Thorne asked the Under Secretary of State for War, on January 10th, for figures showing the number of cases of, and deaths from, typhoid fever, showing separately inoculated and uninoculated among officers and men of the British army

¹ *Journal of Hygiene*, vol. xv, No. 1, 1915.

in the United Kingdom and in France and Belgium since August 1st, 1914, and the date to which the figures were compiled. Mr. Tennant said: The figures I have cover the period from the commencement of hostilities to November 10th. During this period 1,365 cases of enteric fever were reported as having occurred amongst the British troops in France and Belgium; of these, 1,150 cases have been definitely diagnosed after bacteriological examination. In 579 cases where there had been inoculation there were 35 deaths, and in 571 cases where there had not been inoculation there were 115 deaths. In the United Kingdom from August 1st, 1914, to October 30th, 1915, 540 cases of enteric fever were reported and 87 deaths; 39 per cent. of these cases occurred in men who had not been inoculated, but I cannot say how the deaths were distributed amongst the inoculated and uninoculated respectively. For paratyphoid no system of inoculation has yet been adopted.

Employment for Wounded and Discharged Soldiers.—Several questions have been asked recently in the House of Commons with regard to the steps that were being taken to organize a national system for training wounded and discharged soldiers and sailors for trades or occupations, and providing employment for them. Mr. Tennant has stated that men discharged from the army were invited to register at a Labour Exchange if they desired assistance in obtaining employment. The number of men so registered who had been placed in employment was so large that the openings for partially disabled discharged soldiers either in situations or in institutions where training was given were in excess of the number of men eligible to fill them. Mr. Tennant has also pointed out that one of the duties of the Statutory Committee, set up under the Naval and Military War Pensions Act, will be to make provision for the care of disabled officers and men after they have left the service, including provision for their health, training, and employment. The Committee would lay proposals before the Government, and, before formulating them, would consult all persons or bodies capable of rendering effective assistance.

Soldiers Medically Unfit.—Major Glazebrook, in a question on January 10th, asked if men known to be medically unfit were often retained with their units for a considerable length of time before receiving their discharge, and asked whether steps would be taken to accelerate discharge and save upkeep, and so increase the productive power of the country by returning them to their civilian occupations. He also asked whether instructions would be given in the case of groups shortly to be called up to reject without delay after a thorough medical examination those whose fitness was doubtful. Mr. Tennant said that it was obviously desirable to discharge from the army any men permanently unfit, and the Army Council was doing all that it could in that direction. Arrangements had been made for groups of men called up to be examined without delay as to their fitness by special recruiting medical boards, which would not pass or reject any man without a most thorough examination. Mr. Rowlands, by a supplementary question suggested that before a man was discharged to go to the munition works he might be kept for as long as two or three months, but Mr. Tennant did not agree that any specific time could be mentioned.

Sickness in Training Camps.—Sir E. Cornwall asked a question, on January 10th, as to sickness among troops in the Salisbury Plain district since the beginning of September, and whether, in view of the reports as to the condition of the camps, a small committee of the House could be appointed to visit them and report whether improvements were possible. Mr. Tennant, in reply, said that for the period September 1st to December 31st, 1915, the annual ratios per 1,000 for the Salisbury Plain district were: Admissions, 325.4; deaths, 1.88. As both these ratios were lower than those for peace time, he did not think there was any necessity for the appointment of a committee.

Night Noises in London.—On January 6th Commander Bellairs asked the Under Secretary for the Home Department whether, in view of the many sick, wounded, and convalescent soldiers now in London, he would take steps to reduce the noises of London after 9 p.m. Mr. Brace, in his reply, said that most of the noise of London was due to

the circulation of traffic, and could not be satisfactorily dealt with. Legislation would be required to restrict the whistling for taxicabs, but it was hoped that the publicity given to the matter and the good sense of the public would render such legislation unnecessary.

Duty on Alcohol for Medicinal Purposes.—Sir Philip Magnus asked the Chancellor of the Exchequer, on January 11th, what steps he had taken, or proposed to take, to give effect to his promise to remove the duty on alcohol used for medical or surgical purposes in hospitals. Mr. McKenna replied that it was proposed that the relief should take the form of grants from public funds. A committee had been appointed to advise as to the basis of such grants, and would report as quickly as possible.

Potash Salts.—On January 10th, in reply to Mr. Peto, who asked whether any steps were being taken to revive the industry of kelp burning in this country with a view to rendering agriculture less dependent on the importation of potash salts from Germany, the Parliamentary Secretary to the Board of Agriculture said that careful inquiries were made last winter as to the supplies of different kinds of seaweed on the coasts of England and Wales, but the results showed that there was no sufficient supply of seaweed suitable for kelp-making to encourage the Board to proceed further.

Vaccination in Ireland.—In reply to Mr. Patrick Meehan, on January 6th, Mr. Birrell said that he did not think there was any general demand at present for legislation with regard to vaccination in Ireland.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

DURING the Christmas vacation a number of Belgian pharmacists took advantage of a class arranged by the Pharmaceutical Society of Great Britain for instruction in English methods of dispensing and in the reading and translation of English prescriptions. The class, which was entirely gratuitous, lasted from 10 to 4 daily. Professor H. G. Greenish conducted the practical dispensing and Mr. H. S. Phillips the reading of prescriptions. We are glad to learn that the instruction given was much appreciated by the pharmacists who attended, Professor Greenish and Mr. Phillips being repeatedly thanked for the trouble they had taken in making and carrying out the necessary arrangements.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received during the week have been as follows:

	Rs.
B.M.A., South India Branch (per Captain A. J. H. Russell,	
I.M.S., Hon. Treasurer)—	
Dr. Mary Alexander	15
Dr. Margaret McNeil	15
Major Chalmers, I.M.S.	50

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE late Brigade Surgeon Lieutenant-Colonel Joseph Fleming, M.D., F.R.C.S., Army Medical Staff, of Castle-quarter, Inch, co. Donegal, left unsettled personal estate in the United Kingdom valued at £20,316.

ON December 22nd, 1915, Dr. T. J. Walker, of Peterborough, who completed his eightieth year in August, was presented with his portrait in oils, painted by Mr. Fiddes Watt, A.R.S.A. Its cost had been subscribed by 700 friends and neighbours. The presentation was made at a public meeting presided over by Mr. G. C. W. Fitzwilliam, and an address was given by Bishop Clayton. The gift was acknowledged in suitable terms by Dr. Walker, who referred with particular pleasure to the fact that among the contributors were forty ladies who had been nurses in the Peterborough Infirmary, with which he has been so long connected.

THE WAR.

THE PROBLEMS OF MEDICAL EDUCATION IN AUSTRIA AND GERMANY.

VIENNA.

In his opening address to students at the beginning of the winter session in Vienna, Professor Julius v. Hochenegg¹ delivered himself of some scathing remarks to his much reduced audience, which consisted largely of women students. In the previous academic year he had refused to lecture, and he said that it was with great reluctance that he foresaw having to give certificates of attendance to members of his class in this academic year. At the present time, when the great majority of students were fulfilling their duties in the field, and when only a negligible minority, consisting of the medically unfit and women, constituted his audience, he thought the wisdom of giving lectures was questionable.

The Government's Views on Medical Education.

He went on to say that when, in the autumn of 1914, soon after the outbreak of the war, the Austrian authorities decreed that the work of the University of Vienna should continue uninterrupted in every faculty, he had expressed his doubts as to the wisdom of giving clinical lectures, but he favoured the continuation of instruction in the first years of the medical curriculum. It was pointed out to him that the German universities had not discontinued their clinical teaching, and this example was followed by practically all Professor Hochenegg's colleagues, who continued lecturing in the winter term of 1914-15. The difficulties he had foretold became manifest, and the number of students was indeed so small that it was decided for the summer term of 1915 that only one course of lectures should be given on each subject. At a recent meeting of the College of Professors it was decided, in view of the Government's order, that clinical lectures in surgery should be given in Professor Hochenegg's hospital for the winter session. He had therefore to bow to this decision, but he did so under protest.

Military Hospital Work in Vienna.

Since the middle of August, 1914, his hospital had been devoted almost exclusively to the wounded, only two of his eight wards being reserved for civilians. Subsequently accommodation had been found outside his hospital for the wounded under his care, so that the number of beds devoted to the wounded was raised to 492. Before the outbreak of the war his staff consisted of six assistants, two demonstrators, and fourteen operating pupils. At the outbreak of the war he was left with only one assistant and three operators. With this much reduced staff he was expected to do the impossible, and he did not see how, in addition to all the new tasks imposed on him by the war, he could find time for clinical teaching. He could not follow the example of the German universities, where professors engaged in war work had delegated their teaching duties to their assistants. To follow this course in Austria would mean the recall from active service of his assistants, whose services in the field were indispensable.

The Anomaly of Teaching the Unfit War Surgery.

His male audience consisted exclusively of persons rejected for military service. For them only the surgery of peace time was of interest, and, owing to the war, he had not the necessary material on which to base instruction in peace surgery. The thought of using wounded soldiers as object lessons for his students was repugnant to him; for many soldiers the demonstration and discussion of their wounds would be most distressing. Indeed, the pain of these wounds and the risk of infection would in most cases contraindicate their handling by students. Again, the delicate, complicated operations referred to his hospital, including suture of blood vessels and nerves, extractions of deep-seated projectiles, plastic operations, etc., were unsuited for operative demonstration. Merely to look on at such operations afforded little instruction. The conditions for satisfactory clinical instruction were, therefore, wanting for pupil as well as teacher. The present stirring times created an atmosphere of unrest

which was fatal to mental concentration. It would therefore be misleading for him to issue certificates of attendance at the end of a session during which the acquirement of knowledge must necessarily have been below normal. With the war dragging on, it was possible for students to present themselves for examination whose instruction in surgery had exclusively been given under war conditions. It was obvious that their knowledge of surgery must under such conditions be very imperfect.

The Present and Future Supply of Medical Men.

In opposition to these views it has been urged that the war would greatly reduce the number of doctors, and that the gap thus formed would have to be filled. But neither the State nor the individual patient would be well served by ill-trained makeshifts. Indeed, it was not absolutely necessary at once to replace the medical men who had fallen. Before the war practically all the Austrian universities were complaining of a glut in the medical profession, and measures for the limitation of the number of medical students were under discussion. Professor Hochenegg considered that the over-production of the past years would be sufficient to cover the losses of the war. The present number of students was so small that it was negligible as a stop-gap, and this was an additional reason for not encouraging their hasty qualification. During this lengthy war the public had learnt to limit their medical requirements.

Conditions of Medical Practice after the War.

He anticipated that many doctors returning from the front after the war would experience difficulty in regaining their practices. Many would have to start life afresh, for they would find a practice, built up by patient work, lost to them. By teaching the medically unfit stay-at-home, and granting him a medical diploma, harm would be done not only to the medical student in the field, but also to the doctor on active service. Though he was opposed to conferring any benefit on the stay-at-home at the cost of the absentee, he was loth to count medical service in the field as a substitute for training at home; to shorten the medical curriculum, already reduced to a minimum, in this way would, in his opinion, be impossible. In Germany, where the medical curriculum had for a long time included a year of practical work, it was possible to count medical service in the field in this year.

The Duty of the Unfit Medical Student.

He advised his audience to volunteer their services in the many hospitals which were short of doctors and nurses. There they would learn much more than by attending his faulty and improvised lectures. As a student he had spent nine months helping surgeons in the Bosnian campaign; and he was convinced that this experience was the starting-point of his career as a surgeon. Similar experience was now being gained by medical students, male and female, in the present war. About 50 per cent. of the students wishing to attend lectures for the winter session were women. He would like to see nursing made compulsory for women. When he expressed this opinion some years ago it had aroused much opposition on the part of the other sex, notably women-doctors. He did not, however, think that the most sensitive of women would be outraged by his objecting to helping the woman student at the cost of the absent male student. His advice to his audience—that they should go and work in the hospitals rather than attend lectures—was meant to include both sexes. In conclusion, he told those students who failed to follow his advice, and insisted on pursuing their studies and attending his lectures instead of caring for the sick and wounded, that they would find him an exacting and relentless examiner at the end of the term.

URGENCY MEDICAL DIPLOMAS IN GERMANY.

We have already referred² to the steps taken by the German Government at the outbreak of the war to provide an additional number of medical men by granting special facilities to senior medical students. This action appears to have been ill considered and the result of a panic in the Government, which did not allow itself time to consult the medical profession. The Government's action involved the

¹ *Wien. med. Woch.*, November 13th, 1915.

² *BRITISH MEDICAL JOURNAL*, March 6th, 1915, p. 435, and April 17th, 1915, p. 691.

suspension of the "practical year" in the medical curriculum. Between August 6th, 1914, and March 31st, 1915, medical diplomas were granted to 1,273 medical students on urgency or war terms. The average number of medical diplomas granted every year in the period 1908-1914 in Prussia was 625. Had it not been for the war about 745 diplomas would have been given in Prussia, whereas 1,568 were actually given, this number including the medical students who had qualified under ordinary conditions. For the whole of Germany the number of diplomas given for the two years preceding the war were 1,232 and 1,447 respectively, whereas the figure for the last academic year was 3,747. An examination of the statistics for the various German universities before and during the war shows that the standard of efficiency has in many cases been so much reduced by the war that 100 per cent. of the candidates for diplomas satisfied the examiners. For the period 1908-14 only 89 per cent. of the students in Prussia satisfied the examiners. The Bavarian War Office has recently granted furlough to medical students in the field eligible to enter for examinations; the furlough was limited to the period of the examination, and did not include time for study.

BOOTS AND GAITERS.

"GAITER PAIN."

In a reserve hospital for officers in Neuhaus, Schüller¹ observed a number of cases in which the main symptom was severe pain over the tibiae. This symptom, to which he applied the term "gaiter pain," was usually unaccompanied by other symptoms, although occasionally pain in the knee and ankle joints was present also. The pain was bilateral, and, as a rule, equally intense on both sides. It was a tearing or dragging pain, which made itself felt at rest, but which was increased by movements of the legs to such an extent that the patient sometimes could not remain standing. The tibiae were not tender when pressed or struck, there were no abnormalities of the skin, joints, nerves, or muscles, there were no other sensory disturbances, and the cutaneous and tendon reflexes were unaffected. Schüller associated this condition with the wearing of leather gaiters or similar contrivances, but he avoided committing himself to a diagnosis by using the evasive term "gaiter pain."

Kronfeld,² who was attached to an infantry division, states that during the first six months of the war he frequently had the opportunity of observing this condition. The patients usually complained of unbearable "rheumatic pains" in the legs. He was dissatisfied with this diagnosis, but could suggest no alternative. The one to two hundred men suffering from this complaint were much overworked, and naturally anxious not to minimize their symptoms. At this time the claims on the army doctors were so numerous that it was impossible to individualize; and to have put all these men on the sick list would have brought trouble on the head of the certifying doctor. Accordingly, when drugs and other measures failed to banish this symptom, treatment by suggestion and other less gentle methods were applied. Though this Spartan procedure satisfied the authorities so long as the cases were sporadic only, it was neither justifiable nor adequate when the cases increased in number and severity as a result of the winter campaign in the Carpathians. Many cases of frost-bite were observed, but were quite unmistakable and distinct from cases of "gaiter pain."

Dr. Kronfeld observed two cases, which were peculiarly instructive, as he was able to follow them closely. One patient was an infantry officer, who was much debilitated by overwork. Otherwise he was perfectly well, and his limbs had in nowise suffered from frost-bite. The "gaiter pain" in his case could not be altogether dissociated from a history of syphilis. The other patient was a robust, industrious peasant soldier. For weeks he continued to make the same complaints, but repeated examination failed to show anything amiss. Salicyl, quinine, aspirin, embrocations, and massage all proved futile. At last malingering was suspected and, in spite of his complaints of pain, the patient was put on sentry duty. When Dr. Kronfeld inspected the sentries one cold and stormy night he found the patient at his post lying in the

snow, whimpering and groaning with pain. The patient was obviously not a malingerer. He was relieved of duty, and a neurologist, who examined him subsequently and learnt that the patient had been somewhat feverish a little earlier, came to the conclusion that he was suffering from post-influenzal neuritis. Both these patients had worn for months the regulation gaiters, and both cases were typical examples of "gaiter pain."

THE FOOT-WEAR OF THE AUSTRIAN SOLDIERS.

In the course of fourteen months' war, Dr. Kronfeld had travelled about 1,600 kilometres, some 1,200 of which he had walked. This experience had taught him that the best foot-gear was the heavy, hobnailed, watertight laced boot familiar to every tourist and alpine climber. The hobnails were clipped round the margins of the sole, and could not easily fall out. He wore two pairs of socks, and swathed his legs in coarse woollen cloth. To prevent moisture escaping down the tops of his boots he used a strap of cloth or leather, 60 by 10 cm., such as is familiar to every patron of "ski." He had little good to say of the Wellington boots worn by the Austrian sappers and pioneers. The high boots worn by the German "musketier" were no doubt in many respects useful in the bottomless mud of the Russian roads, but they kept out too much air and were difficult to pull off and on, particularly when wet. In his opinion the foot-gear of the Austrian infantry left much to be desired.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died of Wounds.

LIEUTENANT OSCAR GLADSTONE MAGINNNESS, R.A.M.C., died of wounds in France towards the end of December. He was educated at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1913. Previous to the war he was serving in H.M.'s dockyard at Pembroke Dock. He took a temporary commission as Lieutenant from March 27th, 1915.

Died on Service.

Captain William Ernest Rielly, R.A.M.C.(T.F.), died at the Dardanelles on November 28th, 1915. He was educated at University College, London, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1891, and the degrees of M.B. and B.S.Durham, and the D.P.H.Camb. in 1894. After qualifying he acted as house-physician of the Consumption Hospital, Brompton, and prior to the war was in practice at Barnes. He served in the South African war, and held the Queen's medal with four clasps. He had the rank of honorary Lieutenant in the army, and a commission as Captain in the Territorial Force Reserve of the 3rd Battalion London Regiment from March 27th, 1901, but was transferred to serve as Captain and medical officer of the same battalion from September 26th, 1914.

Wounded.

Captain T. W. Wylie, R.A.M.C., Special Reserve (France).

Captain R. E. Walker, R.A.M.C., temporary (France).

Lieutenant G. A. Birnie, R.A.M.C.(T.F.), (France).

Lieutenant A. Wylie, R.A.M.C., temporary (Mediterranean).

Lieutenant L. A. O. Panton, R.A.M.C., temporary (Captain Canadian Army Medical Corps), (Mediterranean).

Lieutenant M. B. Swan, R.A.M.C. (temporary), France.

MEDICAL STUDENTS.

Lauder, Stanislas, Private 14th (London Scottish) Battalion London Regiment, killed in France on October 13th. He was a medical student at the London Hospital, and had passed all his examinations except the final. He served in the Turkish Italian war under the Turkish Red Crescent in Tripoli, and subsequently in a similar capacity in Montenegro in the late Balkan war. He took part in an attack by his regiment on October 13th, was severely wounded while giving surgical assistance to other wounded men, and died while being conveyed from the advanced dressing station to the field ambulance.

Sturridge, Ernest Arthur Leland, Second Lieutenant 8th Battalion King's Own Yorkshire Light Infantry, son of Mr. Ernest Sturridge, of 29, Wimpole Street, and Brondesbury, was recently killed in France. He was a medical student at University College Hospital, where he was prominent in Rugby football and in athletics. He got his commission in the 11th Battalion of the K.O.Y.L.I. on October 3rd, 1914.

¹ *Wien. med. Woch.*, August 28th, 1915.

² *Ibid.*, October 16th, 1915.

DEATHS AMONG SONS OF MEDICAL MEN.

Darbishire, Arthur Duckinfield, Private 15th Battalion Argyll and Sutherland Highlanders, was removed from Gales Camp, Irvine, to the Kilmarnock Hospital, Kilmarnock, on January 2nd suffering from cerebro-spinal meningitis, and died the same day, aged 36. He was a son of the late Dr. S. D. Darbishire, and was born at Oxford in 1879, and educated at Balliol College, taking the M.A. at Oxford with honours in zoology. He subsequently filled posts in the Museum, Oxford, in Manchester University, and in the Royal College of Science, South Kensington. In 1911 he was appointed lecturer on genetics (evolution and heredity) in Edinburgh University. In July, 1915, he enlisted in the 14th Battalion Argyll and Sutherland Highlanders, being transferred later to the 15th Battalion. We understand that he had been recommended for a commission, which he would shortly have received.

Gibbon, Montague Claude, Captain 67th Punjabis, youngest son of the late Lieutenant-Colonel G. C. Gibbon, R.A.M.C., was killed in Mesopotamia on December 9th, aged 51. He was reported at first as wounded and missing, afterwards found killed. He was born on May 9th, 1884, joined the army on January 21st, 1903, and the Indian army on April 10th, 1904, and was promoted to Captain on January 21st, 1912. He served on the North-west frontier of India in the operations in the Mohmand country in 1908, receiving the frontier medal with a clasp.

White, Leonard Hale, Lieutenant R.N., second son of Dr. Hale White, Physician to Guy's Hospital, killed by the explosion on board H.M.S. *Natal* on December 30th, 1915, aged 26. He was educated at Pretherne House and Bradfield College, and passed into the *Britannia* in July, 1904. On completion of his training he went for a cruise in the *Isis*, serving subsequently on the *Majestic*, *Venerable*, *Inplacable*, T.B. 18, *Erne*, *Prince of Wales*, and *King Edward VII.* While in the last ship he formed one of the international landing party which, under Sir Cecil Burney, went to Scutari in 1913. After his return he went through the gunnery course at Whale Island. When the present war broke out he was appointed to command the *Panther*, but was gazetted to the *Tiger* in September, 1914, and was severely wounded in the battle of the Dogger Bank in January, 1915. On his recovery he rejoined the *Tiger*, and served in that ship till December 16th, when he was appointed gunnery lieutenant of the *Natal*, which he joined on December 23rd, only seven days before the fatal explosion.

Combatant Officers Killed.

The list of medical men killed whilst serving as combatants, published in the JOURNAL of December 25th, has been revised and is printed at p. 94. We shall be glad to receive information regarding any whose names have been omitted. A name given for the first time this week is that of Dr. E. M. Ridge.

Edwyn Manners Ridge was born at Enfield in 1877, the son of the late Dr. J. J. Ridge, and was educated at Mill Hill School and at the London Hospital; at both he was well known as a Rugby football player. He took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1900, and after serving as house-surgeon at the London Hospital, and as prosecutor to the examining board of the Royal College of Surgeons, took the F.R.C.S. in 1902. He subsequently filled the posts of assistant house-surgeon at the Poplar Hospital for Accidents and assistant medical officer at Hoxton Asylum, and also held ophthalmic appointments at the London and Royal Western Hospitals, and served as assistant to his father at Enfield. On his father's death in 1908 he continued the practice in partnership with his brother, Dr. R. L. Ridge. In 1911 he joined the Royal Naval Volunteers Reserve as a Sublieutenant; in August, 1914, he was called out for service, accompanied the expedition to Antwerp on October 6th, 1914, and was killed in action there three days after his arrival. The thought cannot but occur that his death in action, though he fell gallantly doing his duty in the service of his country, was a waste of his scientific skill and knowledge, which might have been utilized to better purpose. He leaves a widow and a posthumous son.

LOST AT SEA.

The P. and O. ss. *Persia*, 7,974 tons, Captain W. H. Hull, which left London on December 18th, and Marseilles on December 26th, with the mails for the East, was torpedoed on December 30th off the south coast of Crete, and sank in five minutes, with great loss of life. She had on board 184 passengers and a complement of 317, total 501, out of whom only 166 (crew 101, passengers 65) were saved, and 335 lost. Among the passengers were two lady doctors—Miss Cook, who was saved, and Miss Impey, who was lost. The surgeon of the ship, Dr. Everett, was also among those lost.

Dr. William Everett was educated at Edinburgh University, where he took the degrees of M.B. and C.M. with honours in 1889, and the M.D. in 1893, subsequently filling the post of senior assistant medical officer in the Kent

County Asylum at Chatham. His address is given in the *Medical Directory* as the Headlands, Kettering, Northants.

Miss Elizabeth Stephens Impey was educated at Birmingham University, where she took the degrees of M.B. and Ch.B. in 1911. Afterwards she acted successively as house-physician of the General and Eye Hospital, Swansea, house-surgeon to the Birmingham Maternity Hospital, and to the Birmingham Children's Hospital, and resident surgical officer of the London Temperance Hospital. She had just joined the medical service of the Dufferin Fund in India, and was going out to take charge of the Lady Dufferin Hospital for Women at Lahore. She was the eldest daughter of Mr. Frederick Impey, J.P.

NOTES.

SUVLA AND ANZAO.

In his dispatch dated December 11th, 1915, issued by the War Office on January 6th, 1916, Sir Ian Hamilton makes the following reference to the work of the Army Medical Services:

A feature of every report, narrative, or diary I have read has been a tribute to the stretcher bearers. All ranks, from generals in command to wounded men in hospital, are unanimous in their praise. I have watched a party from the moment when the telephone summoned them from their dug-out to the time when they returned with their wounded. To see them run lightly across fire-swept slopes is to be privileged to witness a superb example of the hero in man. No braver corps exists, and I believe the reason to be that all thought of self is instinctively flung aside when the saving of others is the motive.

LORD FRENCH'S DISPATCH.

Professor Dixon, of Trinity College, Dublin, forwards the following names of members of that school mentioned in Lord French's dispatch of November 30th, in addition to those already noted under the medical services:

Panter, George William, Second Lieutenant 1st Battalion Royal Irish Rifles, third year medical student.

Colhoun, William Albert, Captain 4th Battalion Royal Irish Fusiliers, fourth year medical student.

Brook, Rev. Thomas, M.D., B.D., LL.D., Chaplain to the Forces, third class.

LOSSES AMONG GERMAN AND AUSTRIAN MEDICAL MEN.

In the *Morning Post* for December 29th, 1915, a report was published from its correspondent in Budapest dealing with the official casualties in the German and Austrian army medical services from the outbreak of the war till November 1st, 1915:

Germany.			Austria.		
Killed...	...	96	Killed...	...	101
Wounded	373	Wounded	315
Died of infectious disease	...	707	Died of infectious disease	...	971
Prisoners	215	Prisoners	331
Total	1,391	Total	1,718
Grand total for Germany and Austria ...			3,109		

These figures were given as official during a debate in the Hungarian Parliament. The deaths from infectious diseases appear to have been largely due to epidemics of cholera and typhus. The complaint was made in the Hungarian Parliament that promotion for Hungarian military doctors was too slow; it was said also that not a single professor in Budapest or Vienna, whose services had not been requisitioned, had volunteered for work at the front.

The total loss in the medical service of the German army down to September 22nd, 1915, was recently (see BRITISH MEDICAL JOURNAL, December 4th, 1915, p. 838) stated as 1,027.

GERMAN RED CROSS AND NEW HOSPITALS.

The Central Committee of the German Red Cross has addressed a communication to the management of the International Hotel Owners' Association in which the foundation of special convalescent homes and new institutions for the wounded is discouraged. It appears from this communication that many of these pseudo-philanthropic concerns have been erected and equipped by speculators. The communication proceeds: "The convalescent homes are undesirable for social, political and economic reasons. It is well known that many German baths and therapeutic establishments are hard hit by the war, and that many hotel owners are faced by economic ruin. It seems, therefore, unwise to create a new competitive factor and thus further to injure, however unintentionally, these interests by charitable collections. It is also undesirable to herd the sick, particularly elderly people of good family, in special institutions reminiscent

of barracks. It is not necessary to found societies for the care of combatants. Steps have already been taken to guard the interests of discharged soldiers requiring treatment and unprovided or insufficiently provided for by the military or insurance authorities. Arrangements have been made for the care of invalids in the various institutions and baths on cheap, satisfactory, and discriminating terms, which could not be secured either by new societies or by private persons."

MEDICAL OFFICERS WANTED.

2/1st Highland Mounted Brigade Field Ambulance.

Three medical officers urgently required for the 2/1st Highland Mounted Brigade now sending drafts of officers and men overseas, one regimental medical officer for the 2/2nd Lovat Scouts, and two for the 2/1st H.M.B. Field Ambulance. Full particulars of pay and duties from Captain Mowat, Officer Commanding 2/1st H.M.B.F.A., 2, Mount Street, Diss, Norfolk.

2/1st South-Eastern Mounted Brigade Field Ambulance, R.A.M.C.(T.F.).

Three medical officers are urgently required by this unit. They must be willing to take the Imperial Service obligation. Full particulars as to pay and allowances on application to Major Hamilton, Officer Commanding, 2/1st South-Eastern Mounted Brigade Field Ambulance, Cricket Ground, Canterbury.

2/2nd South Midland Mounted Brigade Field Ambulance.

Medical officers are urgently wanted for this unit, at present stationed at King's Lynn. They must be prepared to sign for foreign service. Applications to Major A. G. Magrath, Officer Commanding 2/2nd South Midland Brigade Field Ambulance, London Road, King's Lynn.

England and Wales.

AFTER-CARE OF CONSUMPTIVES.

MR. J. REDMAN ORMEROD, Vice-Chairman of the Lancashire Insurance Committee, in a letter to the *Manchester Guardian* draws attention to the fact that the Commissioners have decided, in response to representations, to abolish district insurance committees in the Lancashire area, but contends that it is desirable to have some bodies to take up some of the work of the district committees, especially so far as it related to the after-care of consumptives who have been discharged from sanatoriums. The district committees were undoubtedly hampered by two circumstances. In the first place, many of them had charge of areas so wide that it was almost impossible for them to keep in touch with the individual cases of tuberculosis, or, as Mr. Ormerod puts it, "local touch was lost, and local knowledge of and interest in cases was virtually impossible." In the second place, the powers of the district committees were, perhaps unavoidably, very restricted, and the constant reference that had to be made to the county committee was so irksome that the members of the district committees lost much of their interest in their work, and little of any practical value was done by them in Lancashire. Mr. Ormerod goes on to suggest that a better arrangement would be to make the after-care of consumptives the business of the various local health authorities which exist in every urban and rural area, with the addition to each such local body of direct and adequate representation of insured persons. Apparently Mr. Ormerod only includes under the term "after-care" the provision of such conditions of home life and employment as will help to make permanent a cure commenced in a sanatorium, the Insurance Committee continuing, as at present, to be responsible for sanatorium treatment and apparently for all treatment of cases not sent to sanatoriums. But it must be obvious that a considerable number of persons discharged from sanatoriums will continue afterwards to require medical treatment at home, and Mr. Ormerod does not clearly state whether he would have such medical treatment given by the Insurance Committee, as at present, or by the amplified local health authority. If the health authority is to give such medical treatment, then we should have two separate bodies giving treatment to the same person at different periods of his disease, and there would be an inevitable tendency for each body when short of funds to attempt to shift the responsibility to the other. On the other hand, if the local health authority is not to give medical treatment as part of its after-care, but to confine itself to providing proper home surroundings and suitable employment, it is difficult to see any advantage over a properly arranged

system of district insurance committees. Moreover, there is one advantage which the district insurance committees have which would be almost entirely lost on Mr. Ormerod's suggestion—namely, the co-ordinating and correlating influence of the County Insurance Committee. It cannot be said that the small urban and rural health authorities have in the country generally reached anything like a satisfactory state. They are too often ruled by petty local interests and by men who, with little or no knowledge of what should be included under after-care, would refuse to be guided by a few representatives of the insured. Anything like proper co-ordination of their work by the county councils has in practice always been beset with difficulties. On the other hand, the County Insurance Committee has full power to co-ordinate the work of its district committees, and in nothing is such co-ordination more important than when the difficult question arises of finding suitable employment for considerable numbers of convalescent consumptives. Mr. Ormerod agrees, "to a certain extent," that the idea underlying the formation of district insurance committees was a good one. So far it has not had a fair trial, and though in some parts of the country, such as Lancashire, the practical working has not been good, there is even less ground for believing that local urban and rural health authorities have as yet shown themselves satisfactory bodies for taking over a duty which every Insurance Committee out to carry out.

Ireland.

ULSTER MEDICAL SOCIETY.

THE second general meeting of the society was held in the Medical Institute, Belfast, on January 6th. Dr. T. A. Davidson, vice-president, occupied the chair. Three new Fellows and three new members were elected.

Dr. Calwell gave notes of a case of polycythaemia in a woman, aged 43. The extremities were deeply cyanosed; she was emaciated, there was some ascites, and the spleen extended 2 in. below the costal margin. The red corpuscles numbered 7,000,000, the white 16,000; a differential count showed 82 per cent. of polymorphonuclear and 16 per cent. of large lymphocytes. The abdomen was tapped to relieve the breathing, and friction was found over the spleen and in both pleurae; the heart showed enlarged right ventricle and deficient and fixed apex beat. The most probable diagnosis was a polyserositis with chronic indurative pericardio-mediastinitis. Dr. Darling (Lurgan) reported 8 cases of Caesarean section with survival of 7 mothers and 7 children. He emphasized the necessity of doing primary section, and not wait until the uterus had become contaminated by repeated vaginal manipulation. Dr. John Campbell, Sir Alex. Dempsey, Dr. Hicks, Dr. R. J. Johnstone offered remarks, and agreed with the main points in Dr. Darling's paper. Mr. Howard Stevenson read a paper on the open method of treatment of fractures, illustrated by a series of lantern slides. He showed the advantage of bringing the ends into apposition, and the impossibility of doing so merely by splints.

INSTRUCTION OF CRIPPLED SOLDIERS IN NEW TRADES.

It has been decided to open a dépôt for 4,000 wounded Irish soldiers in Tipperary, to which men of the eight Irish regiments are to be sent for post-hospital treatment, on the completion of which they will either return to service or be discharged from the army. Many of those men are unable to take part in the usual outdoor recreations, and in a large number of cases will be unable to return to their occupations. It has been decided to institute elementary instruction in wood and metal working, typewriting, and telegraphy. The Joint Technical Instruction Committee of Tipperary has been asked to co-operate in this work. There are two very fine classrooms in the Central Technical School which at certain hours are unoccupied, and the Committee has unanimously decided to grant every possible facility to the military authorities in the matter.

IRISH WAR HOSPITAL SUPPLY DÉPÔT.

The financial statement read to a recent meeting of the Executive Committee of the Central Irish War Hospital Supply Dépôt showed that it was receiving substantial public support.

Rules for the affiliation and guidance of sub-dépôts were approved.

The Committee of the Irish Farmers' Gift Day has allocated the sum of £250 for the supply of surgical dressings, and the dépôt staff will be kept busy for the next few weeks in getting these supplies ready for dispatch to the Near East. The first consignment has been already sent off, in a large lorry load of strong packing cases and boxes, representing two weeks' work of voluntary lady workers. The dépôt is now in full working order, seven large workrooms being used by the volunteers, of whom about 350 have already registered.

Scotland.

PROVISION FOR DISABLED SOLDIERS IN SCOTLAND.

THE Scottish scheme for providing permanently for soldiers disabled in the war has advanced another stage towards realization. As was stated in the JOURNAL for November 20th, 1915 (p. 763), the scheme originated with the Scottish Veterans' Garden City Association, and aims at enabling soldiers, whose economic value in the labour market has fallen on account of the loss of a limb or some other disability, to find homes and training in some useful work whereby they may supplement their pensions. The Earl of Wemyss, who presided over a meeting of the Association on January 7th in Edinburgh, explained that the movement was not a charity in the ordinary sense of the word, but was an effort in the direction of allowing maimed men to retain their independence on returning to civil life. It was reported that representative committees had been formed in several of the larger cities of Scotland and even in more distant places (America and India). It was announced that a suitable site was available at Longniddry. The first section of the plan which could now be proceeded with would embrace forty houses and two workshops, and extension could take place later. It was unanimously agreed to accept the offer of ground at Longniddry, and the Earl of Wemyss, Lord Salvesen, and Sir Henry Ballantyne were nominated as trustees.

Canada.

STERILIZATION OF WATER BY ULTRA-VIOLET RAYS.

THE use of ultra-violet rays for the sterilization of water was introduced last summer at the military camp at Niagara with most encouraging result, for not a single case of typhoid fever was contracted at the camp. Eleven cases of the disease occurred, but, without exception, the men had been in camp less than eleven days and had come from places where typhoid was present. The water used at the camp was taken from the Niagara River, which gave the usual counts of 5,000 per cubic centimetre, and frequently contained the colon bacillus in 100,000 c.c.m., and not infrequently even in 1,000,000 c.c.m. After exposure to the ultra-violet rays no bacteria were found in 50 c.c.m. of water, but as a precaution two subsequent exposures were made. Chlorination was used before installing the ultra-violet ray, and the high bacterial content of the water made it necessary to use from 1 to 1.4 parts per million, which at times gave an unpleasant taste to the water. Fifteen hundred gallons an hour running past three lamps gave an adequate supply of good water for the camp. The cost of installation was about 20 to 25 cents a head of soldiers in the camp.

THE PATRIOTIC FUND.

During the first year of the war—that is, from September, 1914, to September 30th, 1915, the sum subscribed by the Dominion to the Patriotic Fund for the support of soldiers' families was 5,350,000 dollars—an average of 70 cents a head. This year it is estimated that an average of 1 dollar a head, or a total of 7,500,000 dollars, will be required.

No. 7 OVERSEAS STATIONARY HOSPITAL.

The offer of a stationary hospital for overseas service was made some time ago by Dalhousie University, Nova Scotia, and was accepted recently. The personnel has been recruited from the province of Nova Scotia and the

unit is now in training at Halifax. The list of officers, several of whom belong to the medical staff of the university, is as follows: Lieutenant-Colonel John Stewart, of Halifax, officer commanding; Majors E. V. Hogan and L. M. Murray; Captains J. A. Murray, V. M. Mackay, F. V. Woodbury, E. Kirk Maclellan, John Rankin, Kenneth A. MacKenzie, S. J. MacLeod; Lieutenant K. F. Woodbury, dental surgeon; honorary Lieutenant and Quartermaster Walter Taylor; and honorary Lieutenant S. R. Balcom, dispenser. The non-commissioned officers and men have been recruited from all parts of the province, and include a number of students from King's College and the universities of Mount Allison, Acadia, and Dalhousie. An equipment fund has been opened and it is hoped to collect the sum of 12,000 dols.; a committee, of which Dr. G. B. Cutten, President of Acadia University, Dr. H. S. Mackenzie, President of the University of Dalhousie, Dr. B. C. Borden, President of Mount Allison University, are members, has been formed to direct the disposition of the funds subscribed.

Correspondence.

LEPROSY AND LEPER HOUSES.

SIR,—In your interesting review of Dr. Mercier's Fitz-Patrick Lectures, on p. 54, there appears a geographical error which I beg to point out, and which I have corrected in reviewing the same work in another journal. The "Shireburn Hospital in Yorkshire, for 65 lepers," should read the "Sherburn Hospital, Durham," to which institution the description applies. It is true that there was an ancient ecclesiastical foundation at the village of Shireburn, in Yorkshire, but it was only a very small one, and it was not a leper house. This institution, to which I have the honour of being the physician-in-charge, was founded in 1181 as a leper house by Bishop Pudsey. When leprosy died out in England towards the close of the Middle Ages, the hospital was devoted to charitable purposes, and later still the Charity Commissioners reconstituted it into a modern hospital for medical cases, curable or incurable, together with a large out-patient department, at which there are several thousand attendances annually. At the same time the ancient rule of master and brethren still persists, for there is accommodation for 15 "in-brethren," aged men of good character who have resided within the diocese of Durham, who are cared for in their declining years. There are also "out-brethren" and "out-sisters," as well as a system of educational scholarships. Thus, the Sherburn Hospital has transformed itself in accordance with the altered conditions of society, so that, as a modern chronicler has aptly put it, "the great traditions of the past can be wisely, happily, and usefully combined with the highest aspirations of the present and future."—I am, etc.,

G. NORMAN MEACHEN.

Sherburn Hospital, near Durham,
Jan. 8th.

STATE REGISTRATION OF NURSES AND THE RED CROSS SCHEME.

SIR,—The letter of Dr. Ferdinand Rees is to the point. The whole future of nursing hangs in the balance. Nothing but the immediate State registration of the fully-qualified nurse can ever safeguard the status of the nursing profession. The danger of the untrained V.A.D. worker should be recognized and met.—I am, etc.,

Whitley Bay, Jan. 9th.

NEVILLE A. EDDLESTONE.

THE TONSILS.

SIR,—In his letter on the question of tonsillectomy, appearing in your issue of January 8th, Mr. William Hill, whilst advocating total removal of the glands as the operation of choice in most cases, states that he, in company with most others, "would hesitate to eviscerate the entire tonsillar bed in trained singers and other professional voice producers, on account of the danger of altering the form and deranging the muscular mechanism of the fauces from post-operative adhesions."

I am not quite clear what Mr. Hill desires to convey by the words "entire tonsillar bed," but from the text presume

he alludes to a clean evisceration of the tonsils, and, if so, I would like to point out that, in contravention to the popular fallacy (both lay and medical) about this matter, I have many times totally removed septic tonsils by the blunt dissection method in professional voice producers, both teachers and trained singers, with the invariable result that not alone were the pharyngeal symptoms removed, but that the patient experienced improvement, and often marked improvement, of the voice.

I am ready to admit that the scar tissue which forms in the interfacial space subsequent to operation may, in a certain small percentage of cases, give rise to a slight sensation of tightness in the throat, but I have never known this symptom to be complained of for more than six weeks after operation. Further, it is perhaps conceivable that the patient might require a few lessons on the reproduction of his voice when the end-result of operation was apparent, but I have not yet met with such a case.

I therefore feel justified in contending that provided the surgeon possesses the necessary technical experience, and due care be taken to avoid injury to the surrounding tissues, the patient's profession as a voice user is an indication rather than otherwise for the performance of an otherwise necessary tonsillectomy.

With Mr. Hill's other remarks *re* the much debated questions concerning the tonsils I am in thorough agreement.—I am, etc.,

Cork, Jan. 10th.

JAMES B. HORGAN.

SIR,—Dr. William Hill's letter invites an answer from me, or rather an amplification of my previous letter.

I mean what I said, "the only operation applicable is enucleation." I do not except trained singers or other professional voice users, for the reason that I have never seen permanent derangement of the muscular movements of the fauces and palate follow a properly performed enucleation of the tonsils. One would, of course, be particularly careful in regard to this class of patient, both in considering the question of operative procedure and in carrying out enucleation; but that is all. It must, too, be borne in mind that in cases of chronic disease of the tonsils, especially in adults, there is a concomitant and dependent thickening of the pillars and firm adhesions between the capsule and the sheath of the constrictor muscle, and while any of the septic tonsil and the capsule remain the movements of the faucial muscles will suffer from these disabilities, together with others, not perhaps of a serious nature, such as mild attacks of pharyngitis and laryngitis. Adults, singers, clergymen, teachers, have told me how less easily their voices get tired, and how much less strain there is in singing or speaking since their tonsils were removed. There is another side to this question, and that is our attitude towards the tonsils in those who propose to have their voices trained. The same rule applies. It is not wise to leave part of a diseased structure in the throat. In this matter of trained voice users I am, I know, up against authority, but I am convinced that with our wider knowledge this question is ripe for reconsideration and discussion.

Dr. Hill then deals very clearly and very fairly with the methods of enucleation. First let me say that I do not approve of the method of removal of the tonsils employed formerly, and even at the present time, by some general surgeons, and commended in Dr. Mechan's paper, though I fancy Dr. Mechan's intention was to insist on complete removal of the tonsils, and not to commend a particular method. "According to general surgical principles," in this as in other special regions, has been used to cover much inferior surgery. It is probable that the introduction of the guillotine in the first instance had a double origin—the disfiguring and mutilating results of the general surgeon and the lack of knowledge of surgical procedure in the specialist.

Our aim being to remove the tonsil complete in its capsule, we should see that this result is definitely attained. To do this in every case some method of dissection is necessary. I am aware that in many cases—indeed, I may even allow that in the large proportion of cases in the hands of experts—some of the newer forms of guillotine may effect it. Where the result aimed at is not thus attained, experts like Dr. Hill will complete the operation by the aid of dissection. The dissection method, indeed, is the sheet-anchor after all. But the danger of

the guillotine is—and this is my point—that in the hands of the less expert the incomplete operation of tonsillectomy is perpetuated, though, of course, a tonsillectomy has been performed because an enucleating guillotine was used!

Why, then, use a guillotine at all? The dissection method is simple, can be easily taught, is definite in its result, and can be carried out so expeditiously that I myself almost invariably make use of chloride of ethyl anaesthesia in children. In adults I use either local anaesthesia—with a preliminary hypodermic injection of morphine, omopon, or some such narcotic—or chloroform. And here let me say that I think there is no need for the dangerously deep chloroform anaesthesia which some operators insist on. The method of enucleation I use is the one of combined dissection and snare. If it is desired to control the haemorrhage before removing the tonsil, the snare can be tightened and allowed to remain for several minutes before cutting through the hilum. In this way the result claimed for the haemostatic guillotine can be obtained.—I am, etc.,

Glasgow, Jan. 11th.

ROYAL NAVAL VOLUNTEER RESERVE. PRIZE MONEY.

THE Central Medical War Committee recently addressed an inquiry to the Medical Director, R.N., asking whether Surgeons, R.N.V.R., were entitled to prize money, and, as will be seen from the following correspondence, have received an affirmative response.

December 9th, 1915.

Sir,

At the meeting of the Executive Subcommittee of the Central Medical War Committee held on the 6th inst., we were instructed to submit to you the following questions affecting Surgeons of the Royal Naval Volunteer Reserve, with a request that you would be good enough to supply an authoritative answer which we can give to inquirers:

1. Are Surgeons R.N.V.R. to participate in prize money at the end of the war?
2. If not, are they to receive a bonus at the end of the war?

In regard to this latter question, it is understood that temporary R.N. Surgeons are to have a gratuity equal to two months' pay, and officers of the R.A.M.C.T.F. will also receive a gratuity.

We are, yours faithfully,

N. BISHOP HARMAN,
ALFRED COX,
Secretaries.

Surgeon-General Sir Arthur W. May, K.C.B.,
Director-General,
Medical Department of the Navy,
Admiralty, S.W.

No. 19107. Medical Department of the Navy,
Admiralty,
December 22nd, 1915.

Gentlemen,
I have to acknowledge the receipt of your letter of the 9th inst., and to request you to inform your Executive Subcommittee that Surgeons of the Royal Naval Volunteer Reserve will be treated in the same manner as Surgeons of the Royal Navy in connexion with prize money.

I am, Gentlemen, your obedient servant,
(Signed) ARTHUR W. MAY,
Director-General.

The Secretaries,
Executive Subcommittee of the
Central Medical War Committee,
429, Strand, W.C.

EXCHANGES DESIRED.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT in field ambulance in France, owing to impaired health, desires exchange to hospital at home or in France. Address No. 247, BRITISH MEDICAL JOURNAL Office, 429, Strand, London, W.C.

Major R.A.M.C., at present in field ambulance—second line—wishes to exchange. Hospital, field ambulance, or sanitary company going abroad preferred. Has public health qualification. Address No. 249, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.

A captain (Territorial Field Ambulance), at present on sick leave from the Mediterranean, desires to exchange with an officer holding a hospital appointment in or near London. Address No. 250, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.

THE King Edward VII Hospital, Cardiff, has received one thousand guineas from Captain David T. Lewis, R.A.M.C., to endow a bed in memory of his father, the late Alderman Richard Lewis, of Cartref, Pontypridd, vice-chairman of the Glamorgan County Council. In compliance with Captain Lewis's wish the bed will be used for wounded soldiers during the period of the war. The hospital has also received from Messrs. Watts, coal-owners, a donation of the same amount to endow another bed.

Obituary.

SIR FREDERIC WILLIAM HEWITT, Kt., M.V.O.,
M.A., M.D.CANTAB.,

ANAESTHETIST TO H.M. THE KING.

SIR FREDERIC HEWITT, who died at Brighton on January 6th, was the son of Mr. G. F. Hewitt of Badbury, Wilts, where he was born in July, 1857. He was educated at Christ's College, Cambridge, and began his professional career at St. George's Hospital in 1880. He came there after graduating at Cambridge, where he was a popular and successful member of Christ's College. At St. George's, by securing the Brackenbury Prize in Medicine as well as the Treasurer's Prize and by the distinguished manner in which he held various junior posts, he was marked out for more than ordinary success. His interest becoming early engaged in the subject of anaesthesia and an opportunity offering for favourably pursuing this branch of practice, he secured the post of anaesthetist to the London Hospital, which he held for fifteen years, filling during this period similar appointments at Charing Cross Hospital, the Dental Hospital of London, and the National Orthopaedic Hospital. At his old school (St. George's) the post of physician-anaesthetist was instituted in order to regain Hewitt's services, and he was also appointed Emeritus Lecturer on Anaesthetics at the London Hospital.

He made several important contributions to the literature of the subject. The first, a handbook for practitioners and students, entitled *Select Methods in the Administration of Nitrous Oxide and Ether*, appeared in 1888; it was a small but useful treatise. His chief book was *Anaesthetics and their Administration: A Manual for Medical and Dental Practitioners and Students*, which first appeared in 1893, and still maintains its reputation, the fourth edition having been issued in 1912. It is deservedly popular, as the author deals very clearly with the physiological and chemical questions involved. The use of apparatus is also well described. The author spent, he said, ten years in collecting material for this book, which was founded mainly on his own experience. References are relatively scanty but in all cases judiciously selected. Four years later he wrote a highly practical treatise on *The Administration of Nitrous Oxide and Oxygen for Dental Operations*. He urged that safe and thoroughly efficient anaesthesia for dental operations was of such importance that it behoved every dental practitioner to consider carefully whether the crude method of producing insensibility then in vogue should not be abandoned. In its stead, Hewitt urged the employment of his apparatus, which produced an anaesthesia absolutely safe when properly established. No doubt "properly" is a very important qualification; but though Hewitt, like any other experienced author of a book on a practical subject, could not impart his skill to the reader, he never failed to make his principles and practice perfectly clear. In 1889 Hewitt published a useful table showing points to be considered in selection of an anaesthetic, and in 1895 he contributed to Treves's *System of Surgery* an article on anaesthetics.

On December 8th, 1890, Hewitt communicated to the Royal Medical and Chirurgical Society some clinical observations upon respiration during anaesthesia, with special reference to the causes of embarrassed and obstructed breathing, in which he showed the danger of any marked deprivation of oxygen, such as may be caused by the incautious use of bag inhalers, in fat subjects, and persons with weak circulation or disease involving the respiratory apparatus. Temporarily suspended respiration was much less likely to be attended by symptoms of cardiac depression under ether than under chloroform. Hence chloroform was to be avoided wherever a great quantity of the anaesthetic was likely to be needed. In operations on the throat and nose where ether was inadmissible it was, Hewitt insisted, better to induce anaesthesia with A.C.E. mixture or nitrous oxide and ether, and to keep up insensibility with chloroform than to begin with the latter. The A.C.E. mixture, with a free supply of air, was also the best anaesthetic for beginning on a stout, plethoric, or muscular subject, the administrator continuing with ether from an Ormsby's inhaler when the respirations are becoming deep and uncontrolled.

In February, 1899, Hewitt read another communication before the same society on the effect produced in the human subject by the administration of definite mixtures of nitrous oxide and air and of nitrous oxide and oxygen, which led to an interesting discussion. Last March he took part in a discussion in the Section of Anaesthetics of the Royal Society of Medicine on the influence of preliminary narcotics on induction, maintenance, and after-effects of anaesthesia. He urged that the anaesthetist should see his patient some time before the operation, and insisted that this precaution was particularly demanded when preliminary narcotics were deemed necessary. He agreed that these narcotic drugs assured a quiet induction in a patient indifferent or asleep, a diminished consumption of the anaesthetic, and absence, or at least great diminution, of all deleterious after-effects. Atropine was very valuable in preventing nasal and oral secretions, but Hewitt had become rather shy of scopolamine except where definite pre-anaesthetic stupor was indicated. He was then inclined, provided there were no contraindications, to use morphine and atropine before operations, but considered that morphine was to be rejected when the patient was subject to respiratory difficulties, and in operations on the mouth, naso-pharynx, and throat in which bleeding was likely to occur unless the anaesthesia was light.

Sir Frederic Hewitt was President of the Section of Anaesthetics of the annual meeting of the British Medical Association in London in 1910. He was a member of the committee of the Medical Insurance Agency (429, Strand), and was much gratified by its success to which he materially contributed.

A memorial service was held in the chapel of St. George's Hospital at 2 p.m. on January 12th. It was attended by numerous past and present members of the hospital staff, and by representatives of many of the other institutions and associations with which Sir Frederic had been connected.

Dr. J. BLUMFELD, Senior Anaesthetist to St. George's Hospital, to whom we are indebted for much information included in this notice, states that Hewitt occupied himself most successfully with the instruction of succeeding generations of students. There was, Dr. Blumfeld writes, no part of his proficient work upon which his desires were more set than this to encourage the creation of a body of enlightened and experienced administrators of anaesthetics. He strove sedulously to inculcate the principle that the anaesthetist must approach every case of anaesthesia in the spirit of scientific clinical medicine, and choose and administer his anaesthetics according to the results of careful observation and estimation of all the factors involved in the physical and mental condition of the patient and the operation he is about to undergo. Not the least of Hewitt's merits was that by these endeavours he may be said to have really created a school of anaesthetists, and to have done very much not only to improve the general standard of anaesthetic administration, but also to heighten the regard in which that branch of practice is held. As an administrator Hewitt's chief merit, apart from this scientific as opposed to an empirical method of procedure, was the great care which he bestowed upon every detail. This enabled him to trace to their true cause and to treat in the most appropriate way various factors which may give rise to trouble during the inhalation of anaesthetic vapours. It was this care, allied with a natural kindness of disposition, that led very largely to Hewitt's wide popularity amongst patients, for any one who had undergone an operation for which he had given the anaesthetic was most likely to request his presence again if the second occasion arose. He became, of course, more widely known still to the public by his appointment as anaesthetist to King Edward VII, to whom he administered anaesthetics when Sir Frederick Treves operated for appendicitis in 1902.

Mr. G. R. TURNER, Surgeon to St. George's Hospital, sends us the following appreciation: Hewitt was most conscientious, thorough, and painstaking. He did more to elevate his particular speciality and to put it on a proper scientific basis than any of his predecessors. When operating on any case of his the surgeon had absolute confidence that no anaesthetic trouble or disaster would occur.

He liked to see his future patient if possible before the operation day, and on several occasions he has discussed this matter with me and urged the necessity of it whenever any grave operation was contemplated. As physician-anaesthetist to St. George's Hospital—the first to be appointed—he gave lectures to the students and supervised the department with extreme care and keenness. If ever a patient in the hospital died under an anaesthetic he was the authority to whom the inquiry was entrusted, and he presented always a very full analysis of the medical aspect of the case to the Medical School Committee. Hewitt was very insistent that no hot-water bottles should ever be in contact with a patient recovering from an anaesthetic; the bed was to be warmed by them before the patient was put in it, but none were ever to be allowed to touch him. He gave me an anaesthetic five or six times when I had a serious illness and operations about nine years ago, and I was never once sick afterwards. For this I am still grateful to him. In all school and hospital matters he did his utmost for St. George's, and was practically the founder of the St. George's Hospital Club; he was largely instrumental in getting the recreation ground for the students at Wimbledon, and was for some considerable time the backbone of the *Hospital Gazette*. In private life he was genial, humorous, and well informed, and his death will be deplored by a large circle of friends.

THOMAS BUSHBY, M.B. EDIN., M.R.C.P. LOND.,
MAJOR R.A.M.C. (T.),

HONORARY PHYSICIAN, LIVERPOOL NORTHERN HOSPITAL.

We regret to announce the death, at Leamington, on December 31st, 1915, of Dr. Thomas Bushby of Liverpool. He was born at Rainhill, near Liverpool, some fifty-seven years ago, was educated at Marlborough, and studied medicine at the University of Edinburgh, where he graduated M.B., C.M. in 1880. When he entered practice in Liverpool he became private assistant to the late Mr. E. R. Bickersteth, and remained in this position for several years. Mr. Bickersteth's private practice was an education to any young medical man, as it comprised every branch of medicine. Dr. Bushby's first public appointment was that of assistant physician to the Liverpool Hospital for Diseases of the Chest. He was also for many years surgeon to the Liverpool police, and was much esteemed by the members of the force. Dr. Bushby on his resignation was instrumental in securing an increase in the salary of police surgeons in the city, and in this respect earned the gratitude of the medical profession.

In 1897 he received the appointment of honorary physician to the David Lewis Northern Hospital, which is close to the docks, and receives, besides patients from the immediate vicinity, many seaborne cases of illness, including tropical affections. Dr. Bushby held this appointment till the time of his death, although latterly, owing to the state of his health, he was unable to visit the hospital as he would have wished. In addition, Dr. Bushby was a valued friend and physician to some of the Liverpool nursing institutions and philanthropic agencies. In medico-political matters Dr. Bushby did yeoman service. He acted as one of the Liverpool Representatives at the Representative Meetings of the British Medical Association. Dr. Bushby, quiet as he was by nature, revealed himself not only to be public-spirited, but thoroughly alive to the interests of his profession. His reports to the Liverpool Division of the proceedings of Representative Meetings were models, and those who listened to them felt that Dr. Bushby had given the Division a clear and concise account, lit up from time to time with a spark of humour, all the more agreeable because unexpected. He was also president of the Section of Medical Sociology of the annual meeting of the Association in Liverpool in 1912. Whoever dealt with Dr. Bushby, whether patients, practitioners, hospital colleagues, or directors of companies of which he was medical adviser—for example, Liverpool, London, and Globe, the London and North-Western Railway Company—all formed the opinion that he was a man of sound judgement, great kindness of heart, and straightforward in all his actions. About the beginning of the war his health began to fail, and it was a great grief to him that he could not do his share as Major, attached to the 1st Western General Hospital, in attending to the

sick and wounded soldiers. He felt himself compelled to resign, although it was anticipated that after a period of rest he would be able to resume his duties.

Dr. Bushby was of a rather shy and retiring disposition, and, to those who did not know him well, distinctly reserved. He was inclined to hide his light under a bushel, and did not always readily reveal his knowledge. He was a student in the true sense, and possessed an extensive knowledge of medical literature and the classics. For many years he acted as the local secretary to the New Sydenham Society, now defunct. Not only was Dr. Bushby a well-equipped physician, but he took great interest in diseases of the skin, and his opinion on an obscure case was generally sought. His wide experience gave him a sort of instinct in diagnosis and treatment of disease. When prevailed upon, he had many amusing anecdotes to relate, and very often these scored a point against himself. Dr. Bushby will be much missed by all with whom he was brought into contact, and not least by his colleagues. He held various posts in succession in the Liverpool Medical Institution, and was a vice-president at the time of his death.

The funeral took place at Leamington, and at the same time a memorial service was held in the David Lewis Northern Hospital Chapel. At this service his former colleagues, many of his professional brethren, and members of the Hospital Governing Board were present. An address was given by the Rev. T. Pemberton, M.A., chaplain of the hospital, who took his text from Revelations, chap. 14, verse 13.

Dr. Bushby was married to Mary Wimple, a niece of a well known and highly respected Liverpool merchant, Sir William Bowring, Bart. He leaves a widow and a grown-up son, at present at Sandhurst, and a daughter. The memory of an unselfish man, upright in all his dealings, and of unswerving rectitude, lives long; such a man was Dr. Thomas Bushby.

Dr. W. B. WARRINGTON writes: I was a colleague of Dr. Bushby for twelve years at the Northern Hospital, and should not like his passing away to remain without some small tribute to his memory from me. What impressed me constantly in our long co-operation in hospital work was his great unselfishness in any kind of activity that had to do with the reputation of the hospital or the efficient treatment of patients. One was always certain that his opinions were influenced by a single-minded desire to do the best. He was a courteous and most considerate colleague, and in judgement wise and temperate. We were, perhaps, unusually often associated together in professional work and consulted constantly at the bedside of each other's patients. For many years it was our custom to discuss, together with the students, the nature of the illness of some patient previously unseen by either of us. I think this was a very useful method of teaching; we freely asked each other questions and encouraged the students to do the same. So far as I have the knowledge or capacity to estimate Bushby's professional acquirements, they were very great. Thoroughness in examination and large common sense, illuminated by a most varied experience, were his chief characteristics as a physician. He had many interests in the varied branches of medicine, but I fancy that diseases of the heart and of the skin were rather a hobby with him. He introduced very early into the wards the modern methods of the graphic study of the heart, and was undoubtedly an authority on cardiac pathology. His early death at the maturity of his professional powers is very sad. A grateful and kindly memory will always be associated by his many friends with the name of Thomas Bushby.

GUIDO BACCELLI, M.D.,

SENATOR OF ITALY; PROFESSOR OF CLINICAL MEDICINE,
UNIVERSITY OF ROME.

GUIDO BACCELLI, who died suddenly of heart failure on January 10th, was a descendant of a well-known Florentine family, settled in Rome for more than two centuries, and was himself born in Rome on November 25th, 1832. He was thus in his eighty-fourth year. His father, Antonio Baccelli, was a physician of note, and there was a strong medical strain in his ancestry. In 1848 he entered the Ghislieri College at Pavia. He afterwards studied medicine

in the university of his native city, taking his doctor's degree in 1852. In 1855 he obtained by competition the post of assistant physician to the hospitals, and in 1856, again as the result of open competition, he was appointed to the chair of forensic medicine in the University of Rome. He also lectured on botany and on pathology. He resigned his position as professor of forensic medicine after two years on account of political differences with the Papal Government, and devoted himself to the study of morbid anatomy. When a chair of that subject was founded in the university Baccelli was appointed the first professor. In that capacity he had a great influence in turning the minds of his pupils in the direction of modern scientific methods. In 1863 he was appointed lecturer on clinical medicine, and in 1870, when Rome became the capital of Italy, he was appointed professor of clinical medicine, a post which he continued to hold till the end of his life.

His activity as a teacher and as a very busy consulting physician did not exhaust his abounding energy. In 1875 he entered the Italian parliament as one of the Deputies for Rome, and soon took a leading place as a politician. In 1881 he became Minister of Public Instruction, and held that portfolio four times in all, doing great service to his country by the promotion of far-reaching reforms both of primary and university education. To him Rome chiefly owes the Policlinico, a magnificent pile of buildings, fully equipped for the study of disease. He was also once Minister of Agriculture, Industry, and Commerce. He was prominent as a sanitary reformer, and was at one time President of the Board of Health. He took an active part in the sanitary improvement of the Campagna; for his efforts in that direction he received the thanks of the Italian Parliament. He was a Senator of Italy.

Baccelli was president of the Eleventh International Congress of Medicine held in Rome in 1894. Those who attended that meeting will remember his fine presence, his stately oratory, the dignity with which he discharged the duties of his office, and his princely hospitality. He could discourse in Latin of Ciceronian quality, and was no little proud of the accomplishment. In Grant Duff's *Notes from a Diary, 1889-1891*, there is the following passage: "Bunsen had been much struck by a scene at the great Medical Congress held this year (1890) in Berlin. When the representative of the Italian Government was called, up rose Baccelli—some six foot three high, and broad in proportion. In the deepest of voices he began: Vos medicos Latine alloquor, Latine quia Latinus sum!" On that occasion he conveyed the formal invitation to the Congress to hold its next meeting in Rome. The closing words of the invitation were as follows: "Scientiæ atque artis humanissimæ vexillum consertum in Capitolio, viribus omnigenis fraterno more conjunctis sæculis nationibus immortalæ fulgebit." These words have a melancholy sound at the present day when the banner of science and humanity, torn to shreds by murderous projectiles, stands bare, a grim reminder of a lost brotherhood.

Besides a monograph on Roman malaria, published in 1878, in which his views on the sanitary improvement of the Campagna were embodied, Baccelli was the author of many contributions to medical literature. The variety of his scientific interests is shown by the following imperfect list of his works: A treatise in four volumes on the pathology of the heart and aorta (1863 to 1867); clinical lectures on malaria (1869); subcontinuous fevers, containing his earliest researches on malaria (1876); true empyema (1868); primary cancer of the spleen (in Latin, 1876); a new method of treatment for aneurysm of the aorta (1876); a new symptom of ovarian tumours in general and of ovarian cysts in particular (1876); the transmission of sounds through endopleuritic effusions (1875 and 1877); and State medicine and clinical medicine in ancient and modern Rome (1879); and the paradoxical compensation of cardiac lesions (1894).

In the House of Commons on January 4th the sudden death of Sir G. SCOTT ROBERTSON on January 2nd was mentioned in connexion with a verbal amendment to the Munitions War Bill which stood in his name. Mr. Lloyd George, in moving the amendment, said that members of all parties would have heard with very great regret of the

removal of an honourable and gallant gentleman, who had won great distinction in the public service, and who was highly respected in every quarter of the House.

DR. JOHN MACRURY, well known to naturalists as the author of *The Birds of the Island of Barra and Notes on Ornithology in A Vertebrate Fauna of the Outer Hebrides*, died suddenly in a nursing home at Glasgow on January 4th. He was a Hebridean, born in Benbecula, and he graduated at Glasgow in 1877. After holding the appointments of house-surgeon and house-physician at the Glasgow Western Infirmary and assistant physician at the Glasgow Dispensary for Skin Diseases, Dr. Macrury began practice in Barra, in the Outer Hebrides, where he worked so hard that his health became impaired, and he took a voyage to New Zealand. On his return he settled in Millport, on the isle of Great Cumbrae, in the Firth of Clyde, where he gained an extensive practice among his fellow townsmen and visitors. He was a good shot, sportsman, and a keen golfer. He leaves a widow, and is survived also by his brother, Colonel Colin William Macrury, I.M.S. Dr. John Macrury will be widely remembered by ornithologists all over the world, as he was an authority on birds and possessed a fine collection of eggs.

THE HON. WILLIAM MACKAY, M.D., died at Reserve Mines, Nova Scotia, on November 8th, 1915, after a long, distinguished, and honourable career in the practice of medicine and in public affairs. He was born at Earltown, Nova Scotia, of Scottish parentage, was educated at Truro, and in 1873 received the degree of M.D. from Bellevue Medical College, New York. In 1886 Dr. MacKay was elected to the Nova Scotia House of Assembly, and was chosen leader of the Opposition. He was defeated in 1890, but re-elected in 1894, and chosen leader of the Liberal-Conservative party. In November, 1912, he was summoned to the Canadian Senate. Dr. MacKay continued to practise until a few days before his death. He was twice elected president of the Medical Society of Nova Scotia, and was one of the originators of the first Public Health Act of that province. His son, Major Daniel S. MacKay, M.D., is with his regiment in France.

Universities and Colleges.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examination indicated:

FIRST M.B.—D. D. Anderson, Sarah E. Andrews, Marjorie M. G. Bardett, A. Bearblock, Margada R. Bensande, M. Z. Bochenok, Hylda G. Briscoe, J. L. McK. Brown, G. H. A. P. Clavier, S. Cohen, Alison M. Collic, Catherine A. Cowan, Beryl Dyer, Winifred M. Fawcett, Kathleen Field, P. J. Freilich, I. Frost, N. Gallant, Kate Glyn-Jones, J. Goldberg, Eleanor Graham, T. B. Händel, A. J. Harris, S. E. Harvey, F. Heber, R. W. P. Huxford, Doris M. Howard, Margaret G. Jones, H. C. V. Joy, R. Keene, Mary E. Kennedy, W. E. K. Kirby, Doris G. Knowles, C. P. Lake, Gidal-Leizer Levin, L. O. Sykes, A. W. Taylor, H. B. Thomas, R. Thurst, Nora R. Trouton, Madeline H. J. Umpleby, Dorothea C. Wigfield, G. M. Willey.

* Awarded a mark of distinction in Physics.

NATIONAL UNIVERSITY OF IRELAND.

THE NATIONAL University of Ireland, founded in Dublin by the Irish Universities Act of 1908, gives in its *Calendar* for 1915¹ all the information customarily to be found in the useful but somewhat dry publications of this class. The university has three constituent university colleges at Dublin, Cork, and Galway; in addition it has a recognized college, St. Patrick's, Maynooth. The book will naturally be indispensable to those for whom it is designed.

UNIVERSITY OF BOMBAY.

THE first volume of the *Calendar*² of the University of Bombay contains a mine of information about the regulations, the degrees, the 112 endowment funds, the benefactions, the 22 recognized colleges, and all the other subjects of interest to its present and future members. The second volume consists of many hundreds of examination papers set in 1913-14 for the

¹ Dublin: A. Thom and Co. Ltd. 1915. (Post 8vo, pp. 767.)

² Bombay: Government Central Press. 1915. (Post 8vo, pp. 1278 and 482.)

candidates in its 26 various branches of instruction. Invaluable to students in India, these volumes are of interest to the inhabitants of Great Britain as an indication of the thoroughness of the British Raj.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated:

PRELIMINARY EXAMINATION.—I. W. Arnovitch, Lucretia H. H. Byrne, A. B. Clery, W. E. Colahan, R. M. Corbet, J. J. Clune, T. E. Donovan, A. B. Doyle, T. C. Doyle, A. C. Esmonde, M. W. Frazier, Roberta E. Fisher, W. A. Graham, S. G. Gilmore, T. M. Golden, T. Heffernan, J. Hewitt, Margaret Holiday, P. Killeen, J. J. A. Lord-Flood, T. J. McCormack, A. McLean, H. T. Macaulay, A. Martinson, P. Moylan, R. J. Ogden, P. J. A. O'Connor, T. L. Quinn, J. Rubenstein, G. E. Strahan, J. Sheil, R. T. Taylor, Mary E. Tempst, J. W. Tighe, H. E. W. W. Waters.

SECOND PROFESSIONAL EXAMINATION.—Miss H. G. Rea (with honours), S. H. Berwitz, J. P. Brennan, J. A. Cunningham, P. J. Filose, S. A. Gailey, Miss H. Gleeson, W. J. McElhinney, P. J. McGing, C. Murray, M. C. Myerson, J. C. Rutherford, R. T. Stoney.

THIRD PROFESSIONAL EXAMINATION.—Miss E. Budd, D. L. Crowe, I. B. Cuthane, F. Daly, E. H. H. Lloyd-Dodd, J. P. Doyle, P. J. Flood, H. Hurst, D. C. Kelleher, J. E. Lucas, T. P. McDonnell, M. T. McElligott, M. F. Murphy, M. M. Price, G. W. Pope, G. C. F. Roe.

SUPPLEMENTAL FINAL EXAMINATION.—J. Cohen, J. Dwyer, T. Farrell, O. J. M. Kerrigan, John F. Saunders Magner, T. J. Ryan, J. J. Walshe, P. W. Walshe.

FINAL EXAMINATION.—M. Burke, L. L. Davys, M. de Caestecker, J. A. Fretton, D. L. Kelly, T. F. Moran, V. A. Power, J. Ryan, C. W. C. Robinson.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved at the examinations indicated:

PRIMARY EXAMINATION (PART II).—*Physiology*: R. W. C. Ball, C. C. Bennett, T. G. D. Bonnar, H. G. Burford, N. Chena, A. E. Collie, L. Dinerstein, J. H. C. Eglinton, D. C. Farquharson, G. B. D. St. Gray, G. H. C. Harding, R. A. Hickley, G. H. Johnson, E. H. J. Le Clezio, H. O. Long, A. G. A. Miller, C. Moffatt, A. A. Osman, B. H. Parry, A. L. S. Payne, G. F. Peters, R. S. Ralph, A. H. Richards, S. H. Robinson, H. M. Savory, W. M. Savory, A. G. M. Severn, C. G. D. Siggs, W. H. Simmons, W. Skelly, J. Stephen, W. H. Stevenson, E. W. Terry, C. de B. Thompson, R. A. Walker, R. L. Walker, R. W. Warrick, E. R. Webb, S. A. Withers. *Anatomy*: R. W. C. Ball, C. C. Bennett, T. G. D. Bonnar, C. V. Brown, H. G. Burford, N. Chena, A. E. Collie, L. Dinerstein, J. H. C. Eglinton, F. K. Escriott, D. C. Farquharson, G. B. D. St. Gray, G. H. C. Harding, G. H. Johnson, W. A. Jones, E. H. J. Le Clezio, J. S. Lewis, H. O. Long, W. D. McRae, A. G. A. Miller, C. Moffatt, A. A. Osman, R. H. Parry, A. L. S. Payne, G. F. Peters, R. S. Ralph, A. H. Richards, S. H. Robinson, H. M. Savory, W. M. Savory, A. G. M. Severn, C. G. D. Siggs, W. H. Simmons, W. Skelly, W. H. Stevenson, E. W. Terry, R. A. Walker, R. L. Walker, R. W. Warrick, E. R. Webb, S. A. Withers.

Medical News.

THE Hon. Charles Rothschild, Sir Walter Lawrence, Bt., and Sir Francis H. Champneys, Bt., have been added to the General Council of King Edward's Hospital Fund for London.

THE Society of German Engineers has offered a prize of 10,000 marks, and other prizes amounting altogether to 5,000 marks, for the best artificial arm.

A MEMORIAL service will be held in the hospital church of St. Bartholomew the Less on Thursday next, at 1 p.m., in memory of former St. Bartholomew men and of students of the hospital who have fallen in the war during 1915.

THE names of Dr. T. H. Parke (Tideswell), Dr. C. A. Thorne (Dore), and Dr. W. H. Turton (Heanor) are among the newly appointed magistrates for Derbyshire.

AS Deputy Gresham Professor of Physic, Dr. Harry Campbell will begin a course of four lectures on dietetics at Gresham College, Basinghall Street, on Tuesday next, at 6 p.m.

THE Lettsomian lectures before the Medical Society of London will be delivered by Major F. W. Mott, M.D., F.R.S., R.A.M.C.T., on February 7th and 21st and March 6th, the subject selected being the effects of high explosives on the central nervous system.

PROFESSOR ARTHUR KEITH will begin a course of lectures on the anatomy of the body for first-aid and ambulance students in the theatre of the Royal College of Surgeons, Lincoln's Inn Fields, at 5.30 p.m., on Monday, February 14th. Further particulars can be obtained on application to the Secretary of the College.

AN advanced course of lectures on infant care for voluntary health workers, teachers, and mothers has been arranged by the National Association for the Prevention of Infant Mortality and the Welfare of Infancy (4, Tavistock Square, W.C.). The lectures will be given at the house of the Royal Society of Medicine (1, Wimpole Street), and the course will begin on January 24th.

It is stated that the Russians have transferred the University of Warsaw to Rostow on the Don. The German Government has re-established the University of Warsaw and created a new faculty of medicine.

AT a meeting of the executive committee and members of the Society for the State Registration of Nurses on January 8th, a resolution was unanimously adopted condemning the Red Cross scheme for a college of nursing. A meeting of the central committee for the State Registration of Nurses is to be held on Saturday, January 15th, to consider the matter.

THE Emperor of Japan has conferred the Third Order of the Rising Sun on Dr. William H. Welch, of Johns Hopkins University, and the Third Order of the Sacred Treasure on Dr. Simon Flexner, of the Rockefeller Institution, New York, in recognition of help and guidance given to Japanese students of medicine in the United States, and of their contributions to medical work in Japan.

A HERB-GROWING association, affiliated to the Women's Farm and Garden Union, has been formed to give advice on herb growing and preparation, and by co-operation to regulate the growing of different herbs, so that the market may not be overstocked. Information can be obtained from the Secretary of the Herb-growing Association, 45 (6), Queen Anne's Chambers, Westminster, S.W.

THE name of the firm of Studebaker is well known in this country as the maker of motor cars possessing many excellent qualities, which have been gradually evolved during many years of development. From a small book recently issued, it appears that the firm began some sixty years ago as a maker of wagons strong enough to stand the journey over very rough roads or tracks from the Eastern to the Western States. It is now turning out 60,000 motor cars a year in huge factories. The several processes are carried out in six divisions. The book contains a description of the growth of the system of manufacture and of its present methods. It illustrates four cars—two four-cylinder cars, a four-seated touring and a two-seated roadster, and two six-cylinder cars, a four-seated touring car, and a two-seated cabriolet. The price of the four-cylinder touring car is £295, and the four-cylinder roadster £285. Copies of the book can be obtained on application to the company at 117-123, Great Portland Street, London, W.

SOME time ago the director of the appointments bureau of the Harvard Medical School issued a schedule of questions to 900 medical practitioners who had graduated there since 1900. They were invited to state what they had done, the line of practice adopted, and the amount of their professional income. The object was to obtain suggestions that might help to improve the course of education and the conditions for doctors and the communities served by them. Six hundred answers were received. The average earnings of men who had been thirteen years in practice were given as £936, while the professional income of men in their fourth year was £367, and that of men in their first year was a little over £240. Of the whole number who replied, only 36 had confined themselves strictly to general practice; 134 had combined general practice with a speciality, and 142 were pure specialists. The last number included those who had given themselves up to laboratory work. Of the specialists, 90 were surgeons, 9 gynaecologists, and 9 orthopaedists. One conclusion drawn from the returns is that the local distribution of doctors is not satisfactory, too many choosing large cities for their sphere of work.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology*, Westrand, London; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE SOLDIER'S HEART.*

BY

SIR JAMES MACKENZIE, M.D., F.R.S.,

LECTURER ON CARDIAC RESEARCH AT THE LONDON
HOSPITAL.

THAT the trying life of soldiers, exposed to many and varied vicissitudes, should put a strain upon the heart is what we all recognize. This strain inevitably finds out the impaired hearts, whether the impairment gives rise to physical signs of lesions or not. This is well understood, and, in treatment, presents no feature which has not been recognized in civil life, and about this class of case I do not intend to say anything.

These cases, however, form but a small percentage of the cases that are actually invalidated on account of their hearts. It has long been recognized, particularly since the instructive account published by physicians during and after the American Civil War, that there is a form of heart trouble to which soldiers are particularly liable, and which has gone under the name of the "soldier's heart" or the "irritable heart of soldiers."

Shortly after the outbreak of this war soldiers invalidated on account of heart trouble began to appear in my consulting-room. These were few at first, but as time went on they came in increasing numbers, and I took great pains to find out the circumstances and signs connected with their complaints. These observations brought to light what seemed to me the main cause of the illness which affected the soldiers, so that when I was asked to take charge of the inquiry into disorders of the heart for the medical history of the war, I had before me an object which would give our researches a very profitable aim.

In this work I have been associated with Dr. Wilson, and we have examined about 400 cases. In at least 90 per cent. of the cases that have been certified and treated as heart affections we find that they are not primarily heart cases, and that the principles of treatment applicable to these cases are widely different from those who suffer from heart failure.

SIGNS AND SYMPTOMS.

When we see the soldiers in this country invalidated because of heart trouble we find a good deal of variation in their appearance and symptoms. The face is often lined and drawn; many are spare and thin with a great vasomotor instability, as shown by the manner in which the peripheral circulation varies, the hands and fingers at times going pale and cold, at other times the fingers are thick and red, and the nose likewise becomes red and even blue with slight exposure to cold. If they have been treated for some months by rest and feeding, some become pale, fat, and want of breath.

The chief complaint is an absence of the feeling of being well; they often feel out of sorts—"rotten" is a term frequently employed. A sense of fatigue or exhaustion easily induced is common to all. Breathlessness on moderate exertion is frequent, and more infrequent is pain over the region of the heart. The physical signs are variable. The heart's rate is often not increased; in some it is persistently increased, as frequent as 120 per minute. More frequently, at rest the rate may be quite moderate, but exertion, sometimes slight, may produce an undue rapidity, and it is in consequence of this excitability that the term "irritable heart" has been used.

Murmurs, systolic in time and heard in different regions, are frequent, while an increase in size, usually slight, is not uncommon. In a few cases there is a slight oedema of the legs.

The mental condition is somewhat varied. Periods of depression are not infrequent, and the patients are often very irritable. They accept the view that they have something wrong with their hearts and readily yield to all restrictions, and are often content to lie in bed and brood over their woes.

These are the salient features in a great majority of cases, and you will recognize them as common in civil life. We find identical conditions, for instance, in people recovering from an exhausting illness, as typhoid fever or influenza, or after a severe surgical operation. We

see all these phenomena well marked in people who are suffering from some infective organism, and we also find them in people who have suffered a long mental and physical strain, particularly with insufficient sleep, as in a daughter who has for long periods nursed an ailing mother.

The recognition of the character of these complaints gives us a guide in seeking for the cause of the exhaustion in these invalidated soldiers, and in a great majority of cases we get a history pointing to an illness which preceded their breakdown.

Onset of Symptoms.

The account given of the onset of symptoms is peculiarly instructive. They will say they were in the trenches and felt well and fit until one day they felt seedy and ill, and this continued until they were compelled to seek medical advice, when they were found to have a raised temperature. A few days' relief was obtained, and they returned to their work still feeling far from well, and, after a few weeks of the strenuous life in the trenches, they collapsed, sometimes with loss of consciousness, breathlessness, or even pain.

The story of the onset varies. Sometimes it is an attack of diarrhoea, which persists for a time; sometimes it is after a definite illness, as measles, but most give a history which we can safely surmise as being due to an infection. In a few cases one cannot get such a definite account of the starting of the illness, but many do recognize the gradual onset of the trouble. That is the story of the majority of cases, but there are a number from whom we can get no suspicious history of infection, but where there is an account of a very strenuous life.

To grasp fully how this exhaustion is brought about we must understand the life in the trenches. The story of some of these soldiers is illuminating. One in December, 1914, suffered from appendicitis, and was operated on. He returned to duty three months after, and, in June, went to the front. Immediately on arrival he went into the trenches and was there a fortnight. Every night was spent in repairing the damaged parapets. They were constantly being shelled. He never slept at night, and occasionally got a few hours' sleep in the day, often being twenty-four hours without sleep. One day a shell exploded in the trench, knocking him partly unconscious. On regaining consciousness he stuck to his work for twenty-four hours, but had to give in, feeling weak and ill with pain over the region of the heart.

Effects of Strain during Infection.

So great is the mental strain and bodily exertion, with sleepless days and nights, while the trenches are frequently bombarded, that one might be disposed to consider that these factors would be sufficient to account for all the symptoms. But we find identical symptoms present in many who have never been to the front, and who have had no excessive bodily or mental strain, but who have suffered from some febrile infection. The majority also, as I have said, give a history of some previous illness, and it is necessary we should recognize the effects of strain or effort complicated by febrile illness. For that purpose I recite to you the following experience:

A young officer was training for a foot race, and every day spent some time running round a track. One day, while doing this, he collapsed, fell, and was picked up partly unconscious. A doctor was summoned, who said he had strained and dilated his heart, and that was the cause of his collapse. I was asked to see him, and, after getting this account, I recognized that a man who had taken a considerable amount of exercise the day before could not possibly suffer from heart failure, so I asked him if he felt quite well before he began to run, and he admitted that he felt rather seedy, but hoped to shake off the feeling with the exercise. The temperature was taken and found to be raised a few degrees, so I had no hesitation in stating that the cause of collapse was the toxic influence of some microbe invasion and that, with the subsidence of the fever and a few days' rest, he would be all right. That is what happened, and he was able to resume his training, and ultimately ran his race in perfect health.

The action of toxins produced in the body by bacterial invasions has not yet been clearly worked out, but so far as I have gone into the matter a clear and distinct group

* A paper read in opening a discussion in the Section of Therapeutics of the Royal Society of Medicine on January 18th.

of illnesses can be attributed to the toxins even when the organisms themselves do little damage. The phenomena I have described as characteristic of the soldier's heart will give you an idea of the point I want to establish—that the condition is one of general exhaustion, and the circulatory symptoms are but parts of a general manifestation. To appreciate this more clearly so that we may separate them from those in which there is an actual lesion of the heart, I will call attention to some striking differences between the symptoms of the poisoned heart and the symptoms of the infected heart (that is, where the organisms have invaded the heart) and of chronic disease of the heart.

1. *From Infected Heart.*—In some cases there may be doubt as to whether the condition may not be due to an infection of the heart itself. It may not be possible to settle the question while there is a rise of temperature, so judgement will have to be deferred until the fever subsides. If the temperature remains raised for a period of weeks, and no source of infection can be found, then the suspicion that there is an affection of the heart becomes strengthened. With the permanent fall of temperature, the heart can usually be assumed to have escaped infection and the abnormal manifestations (increased rate, systolic murmur, and increase in size) may be taken as the reaction of the heart to a toxin, or to the factors that produce a general exhaustion.

2. *From Chronic Heart Disease.*—The first sign of a failing heart affected by some old-standing lesion is invariably a subjective one—due to a distressful sensation arising when some effort is made which the individual used to perform with no distress. By far the most common sensation occasioned in this way is breathlessness, the next most frequent, pain. Both these may be associated with palpitation. These are sensations which everyone recognizes as indications of inefficiency of the heart. In the poisoned heart these are usually not the first signs, though they also appear—the first sign being the sense of exhaustion.

The Sense of Exhaustion.

This sensation is often taken as a sign of cardiac inefficiency, but it owes its causation to a different mechanism.

When people suffering from weakness consequent upon an infection, or after an exhausting illness, attempt to walk on the level until they are conscious of their weakness, the sensation by which they perceive their weakness is one of exhaustion or sometimes of giddiness. If they stop, sit, or lie down the sensation speedily disappears. If they attempt a more violent form of effort, as walking quickly or up a hill, or running upstairs, they may be pulled up by breathlessness or palpitation—sensations provoked by heart weakness. It is to the sense of exhaustion and its allied sensations, giddiness and faintness, that I wish to call attention, because the mechanism of production is different from that producing the sensation in patients with primary heart failure.

In people suffering from some toxic influence the central nervous system is always affected. This is shown by the sense of feeling ill, by depression, and irritability of temper. There is also evidence of vasomotor disturbances, as shown by susceptibility of the peripheral circulation—the hands and feet persistently cold, or made so by excitement. There is a persistent over-action of vasomotor influences, as the sense of chilliness that persists after a cold bath; at other times flushes of heat pass over the body, and warmth may tend to over-filling of the peripheral vessels. This is seen in people who faint when standing in a warm room, or who speedily become exhausted or even faint when exertion is made. In these the blood tends to accumulate in the peripheral veins of the limbs and in the large abdominal veins, with consequent anaemia of the brain. It is because of this anaemia of the brain that the sense of exhaustion and syncope is provoked.

I do not enter here into all the facts which support this explanation of the sense of exhaustion, as many observers beside myself have fully dealt with the subject. My purpose here in drawing attention to it is to emphasize the mechanism of its production and to show that it is produced in a different manner from the signs of cardiac exhaustion—breathlessness, palpitation, and pain.

The Character and Meaning of Cardiac Pain.

Another distinctive feature which is occasionally present is a sense of discomfort, amounting sometimes to pain even of a severe kind, felt over the region of the heart. The pain may be occasionally provoked by exertion, but more frequently it comes on when the individual is at rest. Its occurrence, not in response to effort, is characteristic of pain due to a poisoned heart, for angina pectoris due to disease in the young occurs when effort is made. While not absolutely diagnostic, the occurrence of pain, when this type of patient is at rest, is strongly suggestive of poisoning.

Heart Abnormalities are but a Feature in a General Condition.

Taking into consideration all the facts, it will be found that the condition from which certain of these soldiers suffer, who are usually understood to have acquired a heart affection, is not, properly speaking, cardiac in origin, but is the outcome of an injury to other systems as well as the heart, such as the central nervous system. Even when we find such marked abnormalities as increased rate, systolic murmur, and an increase in the size of the heart, the cause of these signs ought not to be looked upon as disease, but merely as part of the manifestation of general illness. The importance of this point of view will be realized when we consider the treatment.

THE CAUSE OF ILLNESS.

While the reason for attributing the majority of these cases to bacterial and toxic influences is so far purely clinical, good grounds can also be found from bacteriological evidence. As, however, bacteriology is outside my province, I will not touch on that evidence further than to point out that I have frequently met with these phenomena in civil life in people in whom the causative organism has been detected.

Here, however, I should like to point out that while the active agent producing these phenomena may be an organism or its toxin, or the products of physical exhaustion, some changes are produced in the economy—in the blood, central nervous system, or heart muscle—which impair the functional activity of these structures. I do not pretend to be able to decide which of these conditions is present, and in any case they do not materially affect the principles of treatment which have been found of value. It is possible, however, that where the illness is due to a microbe, vaccine therapy may be of value; but I am not qualified to speak of this.

NOMENCLATURE.

It is difficult to get a term which will convey clearly what the nature of the trouble is, so I use here the simple one of "general exhaustion."

It is a great misfortune that a custom has arisen that each sick soldier has to be certified as suffering from a definite complaint. Naturally, in the hurry and bustle of the earliest examination, the examining doctor has not the time to make a careful study of each individual. On their immediate breakdown the patients often present features of exhaustion in which the cardiac phenomena stand out most prominently, and the doctor who sees them naturally labels them by these phenomena. It is for this reason, no doubt, that so many of them are invalidated on account of "valvular disease of the heart," "disordered action of the heart," or "dilatation."

My description, like my nomenclature, is very general, and as we inquire deeper into the subject we may be able to distinguish separate groups, each with a definite cause.

TREATMENT.

I have dealt at some length with the diagnosis of these cases, because if we recognize the nature of the illness, then we can readily see on what principles treatment should be based. The lines are those we employ in civil practice. If the patient be the host of some microbe, the treatment should be devoted to increasing his power of resistance. If he be poisoned, treatment should be devoted to the elimination of the poison. Should certain tissues be injured by the invading microbe, or by the toxin or by physical strain, then treatment should be devoted to their healthy renewal.

These indications are practically those which should

guide us in treating individuals after an exhausting illness. We have, however, in addition, to consider the mental condition of the soldier whose experiences have depressed his mental faculties, and who has been told he has some heart trouble. This knowledge always tends to depress, and to make them extremely amenable to that form of treatment that is the worst for them—rest in bed or the avoidance of exertion. If we recognize that such cardiac phenomena as murmurs, increase in size, and variability of rate are but the experiences of an irritated heart, we shall see that too much rest is not beneficial. Every organ benefits by the judicious exercise of its functions, and the heart can also be beneficially stimulated.

The principles of treatment, then, should be devoted to increasing the health of the body as a whole in such a way as to increase the natural resistance to infection, to eliminate toxic influences, and brace up the whole man bodily and mentally. The best way to achieve this is by fresh air and judicious exercise in the fresh air. I need not labour the fresh air idea as it is evident to all, but I want to emphasize the question of exercise.

There is a notion deeply rooted that if there is anything wrong with the heart the patient must be restricted in the amount of effort, and medical men who are themselves afflicted are quite content to lie in bed or move gingerly about.

The line I have adopted with those soldiers who have consulted me is that which I have adopted in civil life. All those I have seen have already been told that their hearts were affected, and this knowledge tended to depress. They often feel miserable, so that there is a mental side to the case, which is aggravated by the supposition that there is something amiss with the heart. This aspect of the case has to be met, and consequently in our treatment this view has to be kept in mind.

When all fever has subsided, or when there is but an occasional rise of temperature, I encourage the patient to get up and go about. I find out the form of outdoor exercise which gives him most pleasure. In my private practice my patients have been officers, so I recommend them to start as soon as possible any form of sport or game which they can get—fishing, riding, shooting, golf, etc.

In recommending such exercise I have two objects in view. The first is the mental condition of the patient, and I need not insist upon the beneficial effects of occupation. The more interesting that is, the more likely is the patient to be taken out of himself. I have referred to the fact that the sense of exhaustion is the predominant symptom in these cases, and that it is probably vasomotor in origin, due to the irritation of the central nervous system. We know that the mental state may play a part in producing exhaustion, for we find that a boring form of exercise will readily produce it, while a form of exercise that is full of interest can be borne for long periods without any exhaustion. Therefore, this out-of-door occupation should be in an attractive form.

In recommending effort, I know it will be said that there is danger in this, just as there was when the soldier was employed in his military duties, particularly when such physical signs as murmurs and dilatation are present. If the true nature of these signs be recognized—that they are but the expression of a temporary enfeeblement of the heart muscle, and that the same measure for restoring a flabby leg muscle applies to a flabby heart muscle—we shall see the importance of exercise judiciously employed. No doubt injudicious exercise may do harm, but there is one precaution of a very simple kind which suffices to prevent any danger, and that is to instruct the patient to indulge in his exercise so long as it gives him pleasure and causes no distress nor discomfort, but to stop or slow down as soon as he experiences the sense of exhaustion, breathlessness, or pain.

This simple and easily comprehended dictum contains in it the whole philosophy of the therapeutics of exercise as applied to the heart, and may be used with safety in all obscure and doubtful conditions of heart weakness.

It will, however, be said that it is all well and good for officers who can afford such means of pleasurable occupation, but what about the private soldier cooped up in the wards? It is for him I wish to prescribe. I used the officer to illustrate the principle so that I may strongly urge that the same principles should be applied to the

treatment of the private. If the officer is depressed and makes but slow progress in his comfortable quarters, what of the private soldier in the gloomy wards, meditating on his troubles, or grouching with his fellows, with an occasional joy-ride in a motor-car? I want this argument for congenial exercise to be fully considered, not only for the pleasure of the sick man, but so that the soldier may speedily regain his health and return the sooner to his duties.

I know that already in convalescent camps the aim of interesting occupation with fresh air is being carried out, and I recommend the same principle to be applied in the so called heart cases. But in these exhaustion may arise too soon for the participation in mechanical occupation, and I would recommend that the same sort of mental stimulus which has been found beneficial in the officer should be employed—that is to say, games. Games absorb the attention and infuse a different spirit from any other kind of employment, and a selection of some games, as bowling, or quoits, or skittles, would add materially to our therapeutic resources.

As a practical outcome of these suggestions, I would recommend that the Government should provide a large hospital for the reception of soldiers who are supposed to be suffering from a heart affection; that these principles of treatment I have detailed should be employed for the recognition of the nature of the complaint, and the principles of treatment here recommended should be carried out.

As soon as signs of improvement are shown, the soldier should begin drilling—at first for a short time each day; and, as improvement goes on, the time increased until he was able to undertake a normal amount. In this way his preparation for fitness would begin early, and he would be rendered fit much sooner than under the present method of treatment.

I would also suggest that this view of the nature of the soldier's heart should be communicated to the medical officers, in order that the diagnosis should be in conformity with the actual condition, and in this way prevent the grievous injury that is done to the sick soldier by implanting in his mind the depressing idea that he suffers from an affection of the heart.

THE IRRITABLE HEART OF SOLDIERS.*

BY

R. McN. WILSON, M.B., CH.B. GLASC.

IN the course of my work as assistant to Sir James Mackenzie, in the inquiry conducted for the Medical Research Committee, I have examined upwards of 200 cases of the condition known as "the irritable heart of soldiers." Careful study of these cases has brought me to the same conclusions as those enunciated by Sir James Mackenzie. I have met what I can only regard as a definite clinical picture, sharply defined and differentiated. The cardinal symptoms he has indicated—great exhaustion after effort; breathlessness on slight exertion; a rapid pulse, which becomes much more rapid upon the slightest attempt at action; pain over the precordial region or along the left costal margin; and a vasomotor condition of greater or less stability—have been present in all my series. I have observed also the tendency to attacks of giddiness to which he drew your attention, the nervous symptoms, the generally high blood pressure, and the tendency to persistence of the condition so long as the soldier is kept confined to his bed.

I propose, therefore, to confine myself to a consideration of the history of the condition, and shall include under this heading the various theories regarding causation that have at one time or another been advanced.

In 1864 the British Government appointed a committee to inquire into the heart conditions prevailing in the army. The committee was assembled by Earl De Grey, and consisted of three generals and two doctors. It sat during the years 1864, 1865, 1866, 1867 and 1868, and issued four reports. In the last the question of infantry accoutrements was considered, and a recommendation was made that the

* Read at a meeting of the Section of Therapeutics of the Royal Society of Medicine.

principle of the brace should be adopted. The idea was that the old form of accoutrement restricted the heart's action. The committee described the condition of irritable heart, which it seems to have recognized clearly as "an extreme excitability of the heart, combined with some, but not great, enlargement. During rest a heart of this kind beats easily, but on the least exertion its action becomes irregular, and the man becomes breathless." The recommendation of the committee regarding the change of accoutrement was later on adopted.

The American Civil War meanwhile was furnishing a large number of cases of "soldier's heart," and in 1864 Henry Harthorne published a paper in the *American Journal of Medical Science* which, I venture to say, furnishes an exact picture of the condition as Sir James Mackenzie has described it to-day. Dr. Harthorne laid stress on the rapidity of the pulse, on the acceleration of the heart's movements on the slightest exertion, on the shortness of breath, and on the cardiac muscular weakness. He suggested that in the soldier the heart was injuriously affected by long-continued over-exertion with deficiency of rest and often of nourishment, and he pointed out that several months of rest and treatment in hospital failed to do more than improve without really curing a large proportion of well-marked cases.

Two causes had thus been suggested so far back as 1864—tight accoutrements and over-exertion. The tight accoutrements were done away with, but the irritable heart remained. I pass over here the contribution to the subject made by Dr. Arthur Myers, of the Coldstream Guards, in 1870, because his description is similar to that already given, and because he also regarded accoutrements as the exciting cause of the trouble. But I must call attention specially to the paper of Da Costa published in 1871 in the *American Journal of Medical Science*. It is the best known contribution to the subject. Da Costa saw upwards of 300 cases in a hospital in Philadelphia, and he affords the following striking picture:

A man, three months or so on active service, was seized with diarrhoea, annoying yet not severe, soon rejoined, and then noticed that he could not bear exertion as well as formerly. Out of breath and unable to keep up with his comrades; dizziness and palpitation; accoutrements oppressed him, yet otherwise he seemed well and healthy. Sought advice; was sent to hospital, where his persistent quick heart confirmed his story. Digestive disturbances, if present, passed away, but the irritable condition of the heart remained, and only very slowly did this get normal or it failed to do so.

Da Costa then proceeded to paint the same picture as that which has been shown to-day by Sir James Mackenzie. He mentioned, however, that he had noted that intercurrent attacks of fever caused the pulse to become less and not more irritable, and to slow down while the attacks lasted.

In 1876 a new phase of the subject was presented when, the change in form of accoutrement having failed signally to effect any improvement, Surgeon Arthur Davy suggested that what he called "setting up" drill was the cause. His theory was ingenious. Setting-up drill, he said, by over-expanding the chest, caused dilatation of the heart and so induced irritability. This view found support in 1880 from Brigade-Surgeon Veale, and again in 1896 from Surgeon-Captain J. B. Wilson, but the discontinuance of setting-up drill does not seem to have put an end to the condition. On the contrary, I have met it in cases in which this cause could be absolutely excluded, the patients having undergone little or no drill.

The theorists, therefore, are bankrupt; the disease remains. More recently we have been asked to view it from the bacteriological standpoint, and more recently still as a condition depending upon faulty action or excessive action of the thyroid gland. I am not in a position to discuss these views, but it is interesting to note in this latter connexion that I have observed that in some eighteen of my cases the thyroid gland was definitely enlarged, and that administration of thyroid extract seemed to exacerbate the symptoms. The application of *x* rays to the thyroid gland is said to have effected improvement in some cases. Let me say, however, that I have seen cases presenting very much the same clinical picture in which the administration of *x* rays did not help matters at all.

In view of the dangers which have attended the making of theories to explain this disease in the past, I am

strongly of opinion that we must preserve an open mind. There would appear to be but one sound method in regard to the condition—the method of prolonged observation and continuous study. Many tempting views suggest themselves, but few stand the test of further investigation.

On the other hand, a few facts seem to have emerged. One of these is that a cheerful atmosphere confers benefit, and a depressing atmosphere exaggerates the condition. The patients are always better when their minds are enlisted in some more or less congenial occupation.

A NOTE ON CERTAIN OF THE VASCULAR PHENOMENA OF CARDIAC DISEASE.

BY

BASIL PARSONS-SMITH, M.D.

THAT considerable importance should invariably be attached to a complete investigation of the blood vessels in all cases of heart disease has long been maintained, and, particularly from the point of view of prognosis, with obvious advantage, for the circulatory mechanism, in its dual constitution of heart and blood vessels, needs a careful and complete study if anything approaching accuracy in the forecast is to be obtained.

Whilst, therefore, every cardiac case that comes before us must undergo a minute examination of the heart itself, its size, rhythm, sounds, etc., our responsibilities do not stop there: we must go further and undertake a rather more generalized study of each particular patient, inquire into the condition of the kidneys and their excretive powers, form some opinion as to the condition of the arterial walls, estimate the blood pressure and pulse tension, and glean additional information from various of the graphic tracings taken from the large superficial vessels, from electrocardiographic records, and by the method of direct vessel auscultation.

The strides which have been made in these latter methods during the past few years are very extensive and widespread in their application; they render possible a diagnostic accuracy hitherto unknown, at the same time facilitating treatment and firmly establishing it upon a sound scientific basis.

With regard more especially to the particular physical signs evinced by the vessels a mass of interesting data is forthcoming; for the purposes of the present communication it is proposed shortly to consider the great venous and arterial channels at the root of the neck and detail a selection of the causes which warrant their very careful study.

In the first place we may conveniently discuss the value of simple inspection, and by so doing formulate a working comparison between the healthy subject and the victim of disease. Reference to the former need but be brief, for the normal neck presents remarkably few noteworthy features; careful inspection discloses results of a singularly negative character; arterial pulsation cannot be made out, and it is only on looking carefully that one can appreciate some slight amount of venous movement, either produced by the external jugular vein, which pursues a superficial course for the majority of its length—in fact, to the root of the neck, where, immediately above the mid-clavicular point, it perforates the deep fascia to join the subclavian vein—or by the internal jugular vein, which, lying rather more deeply in the neck on the outer side of the common carotid artery, may be noticed to visibly pulsate, especially if the overlying sterno-mastoid muscle be relaxed. While, however, this slight amount of venous pulsation may be perfectly obvious in the healthy subject, we must clearly realize that it is by no means a *sine quâ non*, for one frequently notices that it is entirely absent, and unable to be appreciated by naked-eye observation, especially in those normal adults who are possessed of necks nicely proportioned and free from hollows. It seems, therefore, from the foregoing that one must accept both slight venous pulsation and its complete absence as conforming entirely to the healthy state of the normal adult, and, as a general rule, it may be taken that the amount of subcutaneous fatty tissue is the determining factor in every case.

Following inspection one must proceed a step further and endeavour to become conversant with any auscultatory

phenomena which may be normally recognizable at the root of the neck. This question is one which can readily be proved to offer little difficulty: the second aortic sound is clearly heard when one listens over the common carotid artery, also the first sound, which, though perfectly definite, is less well conducted than the former; both sounds, moreover, are better heard on the right side than on the left, as one would naturally expect from anatomical considerations, and both undoubtedly suffer some diminution in intensity by reason of the fact that they invariably mingle to some extent, not only with the respiratory murmur, but also with the venous hum which can so often be detected, especially if the venous channels be large. It is, however, possible, by using gentle pressure, to compress the veins sufficiently to abolish this bruit, but great care must be taken, for if the pressure be excessive the arterial lumen will also be diminished, and a bruit in the artery itself will thereby be produced.

These few remarks explain sufficiently what one must expect, and provide for us a clear mental picture of the characteristics peculiar to health, so that there can be no difficulty in recognizing the various and significant changes which manifest themselves coincidentally with the onset of cardiac disturbances.

That the comparison is striking and self-evident one needs but call to mind the clinical picture which valvular disorders so often present late in their history: the jugular veins, overcharged with blood, stand out in prominent fashion, and over them passes a swift wave-like rippling movement, the visible indication of the state of affairs in the auricular chamber.

This venous pulsation is very frequently of value from the point of view of diagnosis, for its types are many and varied. To mention but a selection will suffice:

(a) The extremely irregular rhythm of auricular fibrillation.

(b) The break of an otherwise regular rhythm by the incidence of premature beats; of the latter, possibly the most evident are those originating in the atrio-ventricular region.

(c) The flickering undulation of high velocity which characterizes the paroxysms of true tachycardia and auricular flutter.

(d) The differing venous and arterial rates of auriculo-ventricular block, several auricular beats being recorded for every one of the ventricle, a physical sign which renders ordinary heart-block diagnosable by means of inspection alone.

One moment's consideration, therefore, will prove that venous pulsation at the root of the neck is by no means a rare phenomenon, being present in health to a slight degree, and in cardiac disorders frequently. Naturally, the extent of the pulsation and the particular amount of venous distension are variable factors and significant at times of widely differing conditions. More often than not a forcible deep inspiration will temporarily empty the distended veins, but there are conditions in which no such effect can possibly be produced, as, for instance, (a) pericardial effusion, if the amount of fluid be sufficient to effectively obstruct the onflow of venous blood to the heart; (b) adherent pericardium, the extreme fibrosis accompanying which spreads slowly and by degrees round the great vessels, tending in time partially to strangle these latter, an effect much exaggerated by deep inspiration; (c) aortic aneurysm, in which the venous overfilling assumes a more permanent quality, tends to be rather more prominent on one side than the other, and extends over a very wide area, possibly including the side of the face, the arm, and the chest wall in varying amounts; (d) new growth, probably a more frequent cause of permanent venous distension than any other.²

Such considerations, therefore, outline the importance attaching to over-distension of the veins. Equally important, however, is the other side of this picture, which, shortly expressed, may be taken to indicate a myocardial failure, the muscle being too weak to maintain even a small amount of venous plethora. This particular branch of the subject has been ably referred to by Stacey Wilson in certain of his recent lectures. He lays special stress upon the signs of heart weakness in later life, when the actual volume of circulating blood is cut down, the area of cardiac dullness is diminished, the loudness of sounds and

murmurs is lessened, the supraclavicular hollows are empty, and the cervical veins are maintained in a state of permanent collapse. Signs such as these, therefore, are the expressions of an enfeebled myocardium, whose mechanical powers have become curtailed to such an extent that a physiological rearrangement has become necessary—namely, an actual decrease in the amount of circulating blood, and a general vascular emptiness; memorable phenomena, in that they are so unlike the physical signs met with in cases of cardiac failure, where, in spite of a general venous distension, hepatic engorgement, oedema, etc., the cardiac muscle continues to contract in vigorous fashion, possessing, as often it does, abnormal powers of resistance.

THE ARTERIAL PHYSICAL SIGNS.

Under this heading it is proposed shortly to consider the diagnostic help which may be acquired by a careful inquiry into the conduct of the large arterial trunks at the root of the neck.

The carotid vessels, whose beat can be accurately located by palpation on a line drawn from the inner end of the clavicle to a point midway between the angle of the jaw and the mastoid process, are sufficiently deeply placed under fascial and muscular coverings that, under all ordinary circumstances, no pulsation is visible. With the presence, however, of certain diseases, notably aortic regurgitation, profound anaemia, exophthalmic goitre, etc., this obviously does not apply; one has only to call to mind an ordinary case of aortic disease to remember at once the intense pulsation visible in the neck in such a case, and, further, that the pulsation is of a peculiarly collapsing quality, an ill sustained wave, especially in the later stages of the disease, so much so that one is persuaded to adopt as a general working hypothesis the fact that the greater the amount of collapse present the greater the amount of regurgitation, and necessarily the greater the progress of the malady. This, however, does not apply to those cases in which the aortic stem and large arteries have become rigid with disease and possibly there may be a progressive stenosis superadded to the original disease; such changes would obviously militate against an excessive pulsation.

This latter subject—namely, exaggerated arterial pulsation—should under no circumstances be dismissed without remembering a fact which seems very self-evident, but which is none the less important—that, when present in consequence of an aortic lesion, it constitutes a bilateral feature, in contradistinction with its one-sided appearance in aneurysm of the carotid artery and also when on one side the normal carotid artery is displaced forwards by some such agent as a neoplasm which causes the vessel to take up a more superficial position. The differential diagnosis between these conditions offers no difficulty when one remembers the generalized implication of the vessels in the one instance and the purely localized signs in the others.

Proceeding next to direct vascular auscultation, and remembering that the heart sounds, both first and second, may be heard quite clearly in the arteries of the neck under normal conditions of health, it does not seem in the least surprising that murmurs may also, at times, become evident. First, the true systolic murmur, which, possibly, of all murmurs is the most readily conducted towards the periphery. This murmur may be produced in one of two ways—either by a true aortic stenosis, or by an aortic dilatation causing a condition of virtual valvular stenosis, with possibly the presence of rigid, rough valves; and with the first of these conditions, the seldom seen true stenosis of the aortic orifice, one hears a rough systolic murmur on auscultating the carotid or subclavian artery in the neck, a marked diminution in the loudness of the second sound, and palpation reveals the conduction of the systolic thrill into the same vessels. The second condition—namely, aortic dilatation with valvular roughening—also yields a loud systolic murmur with upward conduction; but in this case there is no thrill and the aortic sound is accentuated in loudness.

Deserving, moreover, of some attention in the present context are the upwardly conducted murmurs which result from some one of the large variety of congenital lesions—such, for instance, as (1) the murmur produced by pulmonary stenosis, which, resembling the pulmonary

dilatation murmur of anaemia, suffers conduction into the cervical vessels on the left side but not on the right; (2) the murmur of congenital aortic stenosis, and (3) the murmur of pulmonary stenosis, which, complicated as often it is by the patency of a ductus arteriosus, is conducted by the agency of the latter into the systemic vessels, and therefore can be heard clearly in the carotid arteries on both sides.

These considerations concerning the upwardly conducted systolic murmur, with brief reference to the arterial murmurs in exophthalmic goitre and anaemia, lead to an examination of the murmurs which are found in the diastolic interval. It will suffice for this present purpose if we make short mention of the murmur and some of the physical signs associated with incompetence at the aortic orifice.¹ In the writer's opinion, apart from a very natural study of the amount of dilatation present, and also the progress of the sclerotic changes in the heart and vessels in each particular case, one may form a very reasonable estimate of the progress of the malady by a careful investigation of the murmur itself and its routes of conduction. In the early stage one hears the typical murmur following the second sound, and seemingly preventing the valves closing with the usual snap; this murmur is conducted down the sternum apexwards, and auscultation in the neck reveals only the normal heart sounds, possibly the second being somewhat weakened. Stage II arrives with a conduction of the murmur into the vessels—the well known murmur of Duroziez, the first and second sounds being, however, still faintly heard. Stage III differs only from Stage II in that the murmur is more distinct in carotids and the second sound can no longer be detected. This departure of the second sound from the carotid, by preference the right carotid, where one is out of reach of the pulmonary sound, always marks a serious advance of the disease, as does the advent of Stage IV, when one is only able to hear a loud murmur in the vessels, possibly even the double aortic (bellows murmur), by reason of some certain amount of added sclerosis producing a narrowing of the aortic orifice, and the heart sounds are quite inaudible.

It seems valuable, therefore, to listen especially for the normal second aortic sound in the neck in patients with aortic incompetence; also to ascertain if the murmur is conducted into the vessels, its relative loudness in this situation and at the aortic cartilage, and to base one's prognosis upon the results of such an investigation, combined with the ordinarily careful physical examination.

THE VENOUS PHYSICAL SIGNS.

Under this heading we may range a varied and interesting group, the several members of which not only afford valuable comparison with the state of affairs normally obtaining at the root of the neck, but assume an importance equal in every respect to that attaching to the arterial physical signs just enumerated. Visible venous pulsation, so insignificant in the healthy, becomes with disease a striking feature, and may assume, broadly speaking, one of two great varieties—either the positive or the negative type. By these terms one distinguishes the pulsation observed in a vein which is filled during systole—as, for instance, when, with an incompetent tricuspid valve, every contraction of the ventricle reflects, quite unopposed, a wave into the proximal veins—from the opposite type, the negative pulsation, so called because, with the systolic phase, there is a definite venous emptying. As a rule it is quite impossible to differentiate these pulse variations by inspection alone, and, as we shall see later, one can only form an accurate diagnosis if aided by some instrumental method—either a graphic record of the excursions of the vein wall, such as can readily be furnished by any ordinary polygraphic machine, or by the more recently devised method of Parkinson,² who photographs directly the venous pulsation by seating the patient so that the neck is placed directly in the beam of light from an electrocardiograph. By this proceeding one overcomes the disadvantage which sometimes attaches to records obtained by the tambour process—namely, the instrumental delay and possible overswinging—and, in addition, one can simultaneously record the electrocardiogram, thus, for timing purposes, producing a combined tracing of the greatest possible value.

Naturally, however, one cannot invariably obtain these

venous pulse records. There are at times difficulties, as, for instance, with the excessive arterial pulsation of aortic disease, when the venous pulse is quite obscured; also at times of respiratory distress, when, all the accessory muscles of respiration being brought into play, it becomes quite out of the question to attempt any form of tracing at the root of the neck, and in the extreme venous emptiness which is known not only to result from severe heart weakness but also to accompany certain types of adherent pericardium, though in this latter condition one more usually finds a universal venous engorgement, somewhat approaching the condition observed in cases of aneurysm and pericarditis with effusion. These two diseases, however, are somewhat distinct, in that with them venous distension is quite continuous, not disappearing even when a deep inspiration is taken. Moreover, with the presence of pericardial adhesions, the fullness or emptiness respectively of the great veins being determined by the actual position and consistence of the adhesions themselves, one usually finds that the veins are also permanently distended and cannot be emptied, even by a forced inspiration. There is, however, another frequently occurring lesion which participates in the production of venous distension; it is tricuspid incompetence, and the progress of this particular valvular mischief may be very fairly judged by carefully examining the great venous channels connected with the right auricle. For our present purpose we may take the different stages which characterize the condition; its early course, as portrayed by means of ordinary phlebographic tracings, presents no features of note; in fact, the record appears normal. Fig. 1 is an example, and, taken from a

FIG. 1.

patient whose tricuspid valve had for some months been continuously leaking, amply supports the contention; the wave of auricular contraction is well marked, and occupies a normal situation in respect of *c*, the wave caused by the ventricular systole, and this latter is followed at a perfectly normal interval by the *v* wave, which results from the blood stagnating in the auricular chamber prior to the opening of the auriculo-ventricular valves.

When, however, the valvular incompetence progresses we soon begin to notice changes in the venous tracing; the auricle, which at ordinary times was filled solely by the onflow from the veins, is now, in addition, supplied by the regurgitant stream from the ventricle; hence not only is there an overfilling and distension of the upper chamber, but clearly also an auricular filling which is earlier accomplished than formerly it was, and, this being so, one is not surprised to notice that the *v* wave appears prematurely if the tricuspid valve has suffered much damage. To make quite apparent the foregoing remarks one has only to compare the relative positions of the *v* waves in Figs. 1 and 2,

FIG. 2.

which are reproduced to illustrate the first two stages of the condition as recognized by polygraphy.

As time progresses the prominence of the *v* wave becomes more marked, and it merges gradually into *c* wave so that a composite wave is produced, itself ample evidence of the auricular engorgement; but later, and

possibly not until after the lapse of some years, the venous chambers become overtaxed and the auricular muscle, following the protracted period of stress and overstrain, capitulates completely, its wall ceases to contract co-ordinately, and frequently passes into a condition of fibrillation, which, though implying intrinsic activity, is to all intents and purposes useless for the onward propulsion of the blood stream.

FIG. 3.

Fig. 3. is a tracing typical of this advanced stage in the history of tricuspid incompetence; we notice in it—

1. A complete absence of the auricular waves.
2. A fusion of the c and v waves.
3. A similarity between the arterial and venous tracings in that in both one observes a systolic filling and a diastolic emptying, a state of affairs entirely different from that observed at all ordinary times.

Bearing these observations in mind, and admitting that they are by no means comprehensive, but, rather, isolated facts which tend towards and amply warrant a careful study of the varied and widely differing phases which the great veins may assume, one would recommend their careful examination as a matter of routine, especially in cardio-vascular disorders, and, in conclusion, suggest that venous auscultation be not forgotten, for by its aid one gains additional advantages, abnormal sounds become audible—for instance, the well-known *bruit de diable*, characteristic of anæmic states, which, caused by loss of tone in the vein walls, is heard best when the patient is in the standing position, also the upwardly conducted venacaval murmur, the sounds resulting from the closure of the venous valves, and, lastly, the clicking sounds to which the rapidly contracting auricle of auricular flutter gives rise and which are aptly referred to by Morrison as jugular embryocardia.

THE HEART'S ACTION IN JAUNDICE.

BY

J. DAVENPORT WINDLE, M.D.,

SOUTHALL.

THE belief is prevalent that the pulse becomes unusually infrequent and at times irregular in rhythm in jaundiced patients. These changes in the pulse are said to occur commonly in catarrhal jaundice, although met with occasionally in jaundice from other causes. It is curious why there should be this difference if, as is stated, the slowing of the heart is due to the action of bile salts on the heart muscle and intrinsic inhibitory mechanism of the heart.

I have investigated the heart's action in a number of jaundiced patients; in some I have found the pulse infrequent, in some irregular, in others both infrequent and irregular, but I have not been satisfied in any case that the jaundice was responsible for the infrequency or the irregularity. It is said the pulse may fall as low as 40 a minute; if by "pulse" is meant rate of ventricle, this rate, then, must be rare. I have not met with an instance in over 100 cases of jaundice. Slowing of the ventricle to 40 or below, whether occasioned by disease or poison, is, with rare exception, due to partial or complete heart-block, and so far as I know heart-block in the course of jaundice has not yet been illustrated.

A pulse-rate about 50 and 55 a minute is not uncommon in patients with jaundice when free from fever and the patient is kept in bed, but this is not proof that the jaundice is the cause of the slow pulse; the patient's normal pulse-rate must be known, and how it behaves in

other conditions, because the pulse has a tendency to become infrequent in many non-febrile illnesses when patients are confined to bed. The slowest pulse-rate I have met with due to total bradycardia, in an adult with jaundice, was 50 a minute. The patient was a man aged 65, with severe jaundice from gall stone disease; his normal pulse-rate was about 72 a minute. A year after this attack of jaundice he had severe bronchitis with fever and a fast pulse. When he was getting better the pulse fell to 50 to 52 and kept at this rate until he got about again. I could relate many similar examples; on the other hand, in the vast majority of cases of jaundice in adults I have found the frequency of the heart about or above the normal.

In a number of cases I have found a pulse-rate of 40 and below; but the heart-rate has been double the pulse-rate, the infrequent pulse being due to an alternate premature beat of the ventricle too feeble to send a wave to the wrist. This is shown in Fig. 1.

FIG. 1.—Showing two beats of the left ventricle to one of the pulse. A, Apex.

Cases of jaundice with this form of irregularity of the heart and pulse slowing have been published to illustrate the action of the bile salts on the heart, the assumption being that they increase the excitability of the heart muscle, and thus provoke the premature contractions; but there is no other proof advanced, and information is wanting as to the rhythm of the heart before the jaundice occurred and after it had passed off. My own experience indicates no proof that patients with jaundice are more liable to develop extra-systoles than are patients suffering from other toxic conditions. All the cases of jaundice with premature beats I have observed have occurred in persons past middle age; I have not met with any example in a child or young adult, whereas poisons—notably the digitalis group—which in very large doses may produce extra-systoles, do not show this selective action as regards age. In most of my cases of jaundice showing premature beats I know extra systoles were present in health. In some, in which premature beats were noted for the first time during jaundice, I found the extra-systoles persisted long after the patients were free of jaundice, and although this fact does not disprove the provocative action of the bile salts, nevertheless experience has shown that extra-systolic irregularity due to poisons ceases within a few days after the cause is removed. I do not contend that irregularity due to extra-systoles may not be favoured during jaundice—it may be; but I submit it is not because of any action of the bile salts on the cardiac muscle, but because the illness keeps the patient resting. This slows the heart, and premature beats, perhaps only occasional in health, tend to become more frequent with the slower heart action.

As already stated, the pulse is said to be affected more particularly in catarrhal jaundice. This is not a common ailment in adults, and I have notes of only four adult cases; in three of these there was nothing noteworthy in the pulse, in one case sinus irregularity was present. This patient was a woman aged 35; jaundice was marked. In the tracing (Fig. 2) is shown a waxing and waning in rate

FIG. 2.—R, Respiration; I, inspiration; E, expiration.

of pulse, which is 65 per minute on the average. The variations in length of diastoles are independent of the respiratory movements. I have frequently noticed this relation in sinus arrhythmia induced by digitalis, and the irregularity in this case may be due to the jaundice.

I knew nothing of the patient before this illness, but since, I have taken several tracings at rest without finding any irregularity and an average of pulse of 75 to 80.

Catarrhal jaundice in young people is commonly associated with a slow pulse, the rate being often no more than 50 to 60 per minute. The slow pulse is always irregular, and in my experience the irregularity is always due to sinus arrhythmia.

Fig. 3 is a tracing from a boy, aged 13, with catarrhal jaundice; the rate of the pulse is about 52 per minute; the irregularity is of sinus origin. The pulse-rate in health was usually about 80 and irregular in the same way. A year before this record was taken he had scarlet

FIG. 3.

fever, and during convalescence his pulse slowed as much and became as irregular as it did during jaundice.

Fig. 4 is from another case, a boy aged 9; the rate is about 63 and sinus irregularity is present. This boy's pulse is usually about 80 and irregular. He had a pulse of 60 after measles two years later.

These tracings are exemplary of a number I have from similar cases. Sinus irregularity is present in about 80 per cent. of healthy children; those who show it usually have a slower rate of pulse than the average for the age, and there is a curious susceptibility in this rhythm for the pulse to become unduly infrequent under conditions which tend to lower the pulse-rate; during sleep, for example,

FIG. 4.

and after any febrile illness the pulse often becomes very slow and irregular.

In catarrhal jaundice there is usually fever with a rapid pulse before the jaundice appears; when the jaundice comes out the fever goes, and often the pulse suddenly

falls in rate—may be from 100 to 120 with regular rhythm to 50 to 60 per minute in course of a few hours—and

FIG. 5.

becomes very irregular. This naturally attracts attention, and is ascribed to the jaundice; it will generally be found, however, in such cases that sinus irregularity is present in health, and the pulse will behave in the same way in the same patient after any febrile illness; such at least has been my experience.

Poisons which slow the heart have also the power of causing heart-block or hindrance to the passage of a-v impulse through vagus inhibition of conductivity. As already stated, no instance of heart-

FIG. 6.

block during jaundice has been illustrated. In 1911 I had a case of catarrhal jaundice under my care, in which at first there was seemingly impaired a-v conduction, evidenced in the jugular pulse. The patient was a boy aged 13; Fig. 5 is the record taken on the fourth day of well-marked jaundice; the pulse-rate is 75 per minute; impaired conduction is suggested by the lengthened a-c interval, which measures about $\frac{3}{4}$ sec. Next day the rate of the pulse had fallen to 68; in the tracing (Fig. 6) there is an additional wave marked b with the slower beats; careful examination of this curve will show that the lengthening of the a-c interval is apparent only, being brought about by fusion of the waves b and a during the quicker pulse periods. I have illustrated this fallacy more fully in a paper published in 1912.¹

FROM THE VISIBLE TO THE GAMMA RAY SPECTRUM.

By SIDNEY RUSS, D.Sc.,

PHYSICIST TO THE MIDDLESEX HOSPITAL.

(With Special Plate.)

In the accompanying Plate (Fig. 1) is represented a chart of the wave lengths of rays ranging from the visible part of the spectrum to α rays and the gamma rays of radium. The numbers across the top of the diagram represent the number of octaves which the rays range over; the numbers across the bottom give their respective wave lengths in tenth-metres—that is, ten thousand millionth parts of a metre.

The limit of visibility at the red end of the spectrum is 7,594 tenth-metres, and is a convenient starting-point for the purposes of this article; the visible region of the spectrum is constituted by almost exactly one octave of radiation, for the wave length of the ray corresponding to the extreme violet is very nearly one-half that of the extreme red. Passing into the ultra-violet portion of the spectrum, it will be seen that rather more than two octaves have been investigated.

A region of about six octaves, which remains at present unmapped, separates the extreme ultra-violet from the commencement of very "soft" α rays. The most easily absorbed α rays whose wave lengths have been determined are the characteristic rays from aluminium with a wave length of 8.4 tenth-metres. As we pass up through

several octaves of α rays the limit indicated by H is reached; this represents the "hardest"—that is, the most penetrating α ray which has, so far, been produced. The line M represents an α -ray beam of "medium" penetrating power.

The gamma rays from radium are represented in wave lengths as extending between the two heavily dotted lines on the diagram, and it will be seen that the most penetrating gamma rays are of appreciably smaller wave length than the "hardest" α rays so far available. On the other hand, some of the gamma rays are of longer wave length, and therefore more easily absorbed than "very hard" α rays.

The two other lines marked Ca and Ag represent the characteristic α rays emitted by calcium and silver respectively.

One of the objects of this article is to put forward a plea for a more exact specification of the different types of radiation which are used in experimental investigations and therapeutically. It is submitted that the time has passed when it sufficed to record, for example, that exposure to hard α rays caused the disappearance of a malignant growth, or that a lethal effect was observed.

upon some organisms by submitting them to ultra-violet light.

THE X-RAY SPECTRUM.

The data are at hand for introducing an added degree of precision in specifying the type of radiation which is utilized. The matter may be illustrated by an example selected at random. The term "hard x rays" is understood to mean x rays which have a high penetrating power; for the production of such rays a bulb would be run with a parallel spark-gap of about 20 to 25 cm. The radiation from such a bulb is, however, heterogeneous; a screen of aluminium 2 mm. thick will cut out the "soft" constituents, but the rays are not yet homogeneous, for an additional 1, 3 and 5 mm. will cut out various other components of the beam until it becomes practically homogeneous with a wave length of almost exactly 0.2 tenth-metres. The beam of "hard x rays" in these several cases may range over an octave of wave lengths, and different reactions are exhibited by tissues according to whether they are exposed to radiation at one or the other end of the octave. It is suggested that a statement of the range of wave lengths utilized would eliminate many of the uncertainties introduced by such terms as "hard," "medium," and "soft."

Reference may be made here to one difficulty that presents itself with regard to x rays. The question arises as to what regions of wave length are to be assigned to the radiation which is commonly known as "soft," "medium," or "hard." Reference to the diagram shows that x rays have been mapped over a region of about $5\frac{1}{2}$ octaves. The rays "characteristic" of aluminium (8.4 tenth-metres) are "very soft," for they are absorbed by a few centimetres of air; in fact, over the three octaves from this starting point the radiation might be termed "very soft." The next octave—namely, from 1 to 0.5—includes the characteristic rays from platinum and a good part of the unscreened rays from a "soft" bulb (5 to 10 cm. spark gap). The next octave would then comprise "medium" rays; any radiation of smaller wave length than 0.25 could safely be considered as "hard." This subdivision is quite arbitrary, and it is hoped that the Röntgen Society will make some definite recommendations on this subject in the near future.

We may briefly consider the remaining features of the diagram. It will be seen that a portion marked "unmapped region," which comprises about six octaves, separates the extreme ultra-violet from the very "softest" x rays. There are good reasons for believing that other vibrations in this region, that is, of wave lengths ranging from 900 to 9, are very easily absorbed by matter, and this is no doubt, in part, the reason why the other properties of these vibrations have not yet been investigated. Such radiations, however, should not be dismissed from our minds, for it is by no means unlikely that these six octaves of radiation play some part in the reactions of tissues, when they are exposed to the x rays or the rays from radium. If we may apply the information which has been gleaned from the x ray spectrum we might suggest that the amount of this "unmapped" radiation excited in tissues depends not only on the intensity of the beam of x rays, but to a very large extent upon the particular wave lengths utilized. The main chemical constituents of most tissues are essentially the light elements, and all the evidence goes to show that the secondary x rays given out by them under the influence of a primary beam would be very easily absorbed; these rays may even be so slightly penetrating as to be mainly absorbed within the cells from which they originate. Now it is safe to say that more of such radiation would be provoked by a beam of "soft" x rays than by a "hard" beam of equal intensity. Such a secondary process, initiated by the primary beam, may in fact play a dominant part in determining what is spoken of as the reaction of the tissues. The fundamental fact that the human skin when exposed to "soft" and "hard" x rays of equal intensity reacts in an entirely different manner has not, so far, received a rational explanation, and it may be appropriate in this connexion to invoke the above probability which is suggested by general considerations of the spectrum.

THE DANGERS OF X RAYS.

Let us now turn to a second aspect of this spectrum, which impresses one more and more of its potentiality for harm as well as for good.

D

When the first warning was sounded of the damage which x rays did to operators who were insufficiently protected from them, additional precautions were taken to obviate the dangers as far as these were known at the time. The range of ray which may be utilized has, however, greatly widened as the result of investigation, and this is especially the case for radiation of a high penetrating power. It may well be questioned whether the precautionary measures have extended simultaneously with the wider range of radiation utilized and with the more exacting conditions under which so much of the present x -ray work is conducted.

There are two main aspects of the application of x rays which may be briefly considered. When the rays are administered therapeutically it is a desideratum to be striven after that whoever dispenses the ray should receive no fractional part of the dose given. This becomes increasingly difficult to secure when the more penetrating rays are used, and it is precisely when the step is made from one phase of x -ray therapy to another, such as from the treatment of superficial conditions to what is known as deep-therapy, that it becomes necessary to reconsider the efficiency of methods of protection which, eminently suitable for the former, are inadequate for the latter. When it is borne in mind that "hard" x rays have a penetrating power so high that the intensity of a beam is only cut down to 10 per cent. of its intensity by going through about 12 or 13 cm. of tissue, the difficulty of adequate protection from such radiation will be apparent.

When we turn to the other aspect of the utility of the rays, namely, in radiographic and screen work, the dangers are of rather a different character, though no less real.

The conditions under which the radiographic work necessitated by military affairs is conducted are often very exacting, and this is particularly the case in screen work; such procedure involves the proximity of the operator to the bulb, and however efficient the protective devices may be, it is almost impossible to arrange that the operator does not become irradiated to some small degree. The protective devices cannot be pushed to the limits which are possible under other conditions, for the gloves worn by the operator must not be so cumbersome as to hinder his manipulations, the lead glass of the screen which protects his face must not be so thick as to interfere unduly with the visibility of the picture he interprets, and so on. Again, it has to be recognized that an installation which provides reasonable protection to any one engaged upon it for short or intermittent periods may be quite inefficient when use is made of it for periods of a good many hours per day.

In the light of our present knowledge it cannot perhaps be stated what is a safe limit for an operator to be the daily recipient of in the way of x radiation, but it would appear certain that unless stringent precautions are taken, damage—perhaps irremediable damage—will be done to those who are engaged in one of the branches of medical work the importance of which can hardly be overestimated.

ULTRA-VIOLET RADIATION.

Ultra-violet rays have been investigated over a range of rather more than two octaves. The first octave beyond the visible portion of the spectrum, with wave lengths from 3,800–1,900 A.U.,* is the region of therapeutic interest, for the radiation beyond this, and forming the second octave, is so easily absorbed by air that investigation of it has to be carried out in a vacuum.

In Fig. 2 are reproduced photographs of the ultra-violet radiation from various arcs taken by means of a quartz spectrograph. They are respectively (1) mercury, (2) silver, (3) copper, (4) the Simpson arc, and (5) carbon. It will be seen that the spectrum of mercury vapour does not extend quite so far as that of silver, which, again, has not so large a range as copper. The Simpson arc consists of pole pieces of wolframite, the main constituent of which is tungsten. The radiation from this arc is very rich in ultra-violet rays, and an examination of it shows that it consists of a large number of emission lines which do not vary locally very greatly in relative intensity from one another, although the photographic intensity of the rays gradually fades off toward the region of short wave lengths. The general character of the spectrum of the Simpson arc appears, therefore, to be one rich in ultra-violet radiation, which is graded fairly uniformly throughout the region

* A.U., that is, Angstrom unit, is one-tenth metre.

under consideration; this is in marked contrast to the arc spectrum of copper, which is seen to consist of groups of very bright lines, with considerable intervals between them. The carbon arc (5) is seen to have a somewhat restricted range of ultra-violet radiation.

THE PENETRATING POWER OF ULTRA-VIOLET LIGHT.

When any of the various sources of ultra-violet light are used therapeutically the question arises as to how far the rays are able to penetrate through the tissues. It has long been known that blood pigments are strongly absorbent of such radiation, and means were accordingly taken to prevent, as far as possible, direct access of the blood to the part receiving the rays.

It seemed desirable, however, to make some measurements of the extent to which the ultra-violet rays penetrate the skin. For this purpose skin removed from the human abdomen was used; it was cut parallel to the external surface in layers $\frac{1}{10}$ mm., $\frac{1}{2}$ mm., and $1\frac{1}{2}$ mm. thick by means of a large-sized microtome; these different thicknesses of skin were then placed in front of the slit of the spectrograph, to ensure that any radiation entering the instrument and affecting the photographic plate placed in position, would first have penetrated the particular thickness of skin.

The source of ultra-violet radiation selected was the Simpson arc. When this was placed about 20 cm. distant from the slit of the spectrograph an exposure of a few seconds was sufficient for a photograph of this radiation as far as wave length 3,000. In order to bring out the very short wave lengths the plate has to be rather over-exposed in the violet region (see Fig. 3, No. 1). The exposure in this case was 5 seconds.

It was soon found that skin was very absorbent for the ultra-violet radiation, and consequently the time of exposure had to be much increased in order to obtain any record on the photographic plate. Fig. 3, No. 2, shows the result of interposing $\frac{1}{10}$ mm. of skin in front of the slit of the instrument; the exposure was increased from five seconds to two minutes. No. 3 and No. 4 show the results for a thickness of $\frac{1}{2}$ mm. and $1\frac{1}{2}$ mm. respectively; the exposures were in each case eight minutes—that is, nearly one hundred times that of the unscreened radiation. In spite of this, however, a large portion of the spectrum is cut out.

It will be seen, therefore, that ultra-violet rays of wave lengths 2,100 to 3,000 A.U., the approximate positions of which are indicated in Fig. 2, are very easily absorbed by human skin; certainly less than one part in a thousand of this radiation penetrates to a depth of half a millimetre.

As we proceed to the region of wave lengths 3,000 to 3,800 A.U., which latter marks the onset of visible radiation, the rays become rather more penetrating, but it is doubtful whether as much as 1 per cent. of the radiation penetrates as deep as 1 mm. Fig. 3, No. 4, shows, however, that a small percentage of ultra-violet radiation penetrates $1\frac{1}{2}$ mm. of human skin.

THE SPECTRUM OF THE SIMPSON ARC.

The poles of the Simpson arc are said to consist of wolframite, a prominent constituent of which is tungsten.

In order to see to what extent tungsten contributes to the ultra-violet radiation from the Simpson arc, two electrodes of pure tungsten were obtained, and the arc spectrum photographed in the same way as indicated above for the Simpson arc.

In Fig. 4, No. 1 is a photograph of the spectrum of the Simpson arc, between wave-lengths 5,800 and 2,100 A.U. No. 2 is a photograph of the spectrum of a pure tungsten arc over the same region; the exposures were for five and ten seconds respectively.

Inspection shows that the two spectra are apparently identical. Whether there are differences in the relative intensities of the emission lines cannot be said without a more extensive examination.

THE last report of the librarian of the Harvard Medical School states that 3,100 volumes have been added to the collection during the past year. The library now contains 27,000 volumes and 46,067 pamphlets. The College of Physicians of Philadelphia has 105,540 volumes; the New York Academy of Medicine, 100,320; the Boston Medical Library, 83,107; and the Johns Hopkins Hospital, 17,000.

SODIUM HYPOCHLORITE IN THE TREATMENT OF SEPTIC WOUNDS.

BY

FLEET SURGEON FREDERICK J. A. DALTON, R.N.

IN September, 1915, a committee was sent to the Gallipoli peninsula in the naval hospital ship *Rewa*, by order of the Medical Director-General of the Navy, to report on the efficacy of hypochlorites in the treatment of infected wounds. The committee made two trips to the beaches in this ship—one to Anzac and one to Cape Helles. Unfortunately for their purpose, there was at this time very little attacking going on at the peninsula, and although 1,176 patients were carried in the two trips, the majority were cases of dysentery, enteric, and epidemic jaundice, and the proportion of wounded to sick was very small. The committee returned to England on October 18th.

Before leaving, Dr. H. D. Dakin, who was working in connexion with the Medical Research Committee, asked me to continue the investigation of the value of hypochlorites as opportunity offered on this ship, and this has been done.

In the past two months we have carried an additional 2,753 cases to Alexandria and Malta, but of this large number only a very small percentage have been wounded.

Every wounded patient received on board during this period, whose wound or wounds were clinically septic on arrival, has been treated with the special sodium hypochlorite solution prepared according to Dakin's formula. No other form of antiseptic was employed. Although this report is based on the small total of 57 cases, the results have been so uniformly and consistently good that I think it may be useful to publish it now, in order that the hypochlorite solution may be more generally used in the treatment of wounds than is the case at present.

Wounds that were clinically clean on arrival on board were also irrigated with the sodium hypochlorite solution and dressed with gauze soaked in the antiseptic. But these cases are not considered in connexion with this report since they would probably have remained clean and healed with any other form of customary dressing, and therefore cannot be counted as evidence in favour of hypochlorites being far superior to any other form of antiseptic that we have so far used on board this ship; that being the point I wish particularly to bring out.

Before employing the sodium hypochlorite antiseptic, my colleagues and I in this ship used various weak antiseptic lotions for the thorough irrigation of these large septic wounds, each fancying his own pet solution—be it carbolic acid, perchloride of mercury, etc.—gave the best results. My own predilection was for passing pints of ordinary sterile salt solution through the wound. Since making trials of the hypochlorite solution there has been absolute unanimity among us as to the preference for it, and we all now use it as our routine lotion.

Preparation of Hypochlorite Solution.

The antiseptic solution is made on board from dry carbonate of soda (United Alkali Co.'s best soda ash), bleaching powder of good quality, and boric acid, according to Dakin's directions given in the *BRITISH MEDICAL JOURNAL*, August 28th, 1915. The solution was made in large carboys holding about 40 litres.

Five hundred and fifty grams of the carbonate of soda were dissolved in a carboy half filled with fresh water; 800 grams of bleaching powder were then added, and the mixture thoroughly shaken for five minutes. The carboy was then filled up with fresh water, and, shaking the mixture once more, it was allowed to settle for half an hour. The clear fluid over the precipitate of calcium carbonate was siphoned off as completely as possible, and filtered into a second carboy by passing through a plug of cotton in the neck of a large funnel; 150 grams of boric acid were added to the filtrate, and the mixture was then ready for use. It was drawn off from the carboy as needed by means of a siphon.

The solution was never kept longer than a week, and any unused solution that had been made longer than a week was thrown overboard. This waste is a matter of no moment since the cost of the preparation is so extremely small.

Method of Use.

The usual surgical procedures were adopted for enlarging the wound, making counter openings, removing portions of detached bone, foreign bodies, including bits of clothing, fragments of shell, bullets, gravel, etc. Every portion of the wound was then thoroughly irrigated with large quantities of the hypochlorite solution. One or several rubber tubes, according to the nature of the wound, serving for the introduction of the hypochlorite solution, were then inserted, and strips of gauze arranged around the tubes and lightly packed into every portion of the wound. It is essential that this should be properly done, the idea being that the gauze strips function simply as wicks to convey fresh hypochlorite during subsequent treatment to every surface of the wound.

The outer surface of the wound is then dressed with gauze lightly wrung out in the hypochlorite solution. The ends of the rubber tube or tubes are brought out through the gauze dressings, a bandage lightly applied over all to keep tubes and dressing in position, and the ends of the tubes brought out through the bandage, to serve for the subsequent renewal of the hypochlorite.

In profoundly septic cases the hypochlorite solution is injected into the tubes, by means of a glass syringe, every two hours for the first twenty-four to forty-eight hours, and subsequently less frequently as the wound begins to clean up. In less severe cases we find by experience that syringing with hypochlorite at four-hourly intervals suffices. Each case should be treated, so far as frequency and quantity of hypochlorite administration is concerned, with regard to the size, nature, and septicity of the wound. The object aimed at is to supply every surface of the wound with a sufficiency of fresh hypochlorite solution as often as required.

In bad cases the gauze strips are renewed after the first twenty-four hours. With slighter wounds they may be left in for three to four days, and then usually do not need to be replaced by fresh strips, as the wound generally cleans up with simply occasional squirting of fresh solution into the tubes.*

NOTES OF CASES, ETC.

The cases were under the personal care of Staff Surgeon Fisher, R.N., temporary Surgeons Smith and Beaton, R.N., and Surgeons Gilbertson and Chitty, R.N.V.R. They comprise a great variety of bullet, shell, shrapnel, and bomb wounds, and a number of cases of gangrene following frost-bite. In addition, several stinking appendix abscess cavities were successfully treated with careful irrigation and swabbing with the hypochlorite solution.

It does not seem worth while to reproduce the case notes in full, since this would involve much needless repetition. A few typical cases are selected, to which are added the notes of the surgeons in whose care the patients were.

The use of hypochlorite in cases of frost-bite with broken skin, or where gangrene and sloughing have supervened, appears to be distinctly valuable. Sloughs are rapidly removed, and it accelerates the production of healthy granulation tissue. In gangrenous cases its deodorant action is very marked, but it is important that severe cases should be treated not less frequently than four-hourly. A single typical case is briefly noted at the end.

CASE I.

H. R. D. Gunshot wound of lip, neck and vertebrae, piercing first rib with exit over sixth dorsal spine. A haematoma of the neck was cleaned out and hypochlorite injected into the cavity at frequent intervals. After four days there was no sign of pus, and the hypochlorite dressings were applied only twice daily.

CASE II.

A. H. G. Septic wound of left buttock with cellulitis. Operation November 29th. Wound was opened up, leaving very dirty sloughy surface, 6 in. long, with foreign bodies in it. Hypochlorite was applied four-hourly. The cellulitis rapidly cleared up, and in four days the wound was covered with clean granulations.

CASE III.

M. R. Compound fracture of left upper humerus. The patient was admitted December 15th, after treatment on shore for one week. The wound was septic, with much pus and oedema of arm. The hypochlorite was given three-hourly.

* Information relative to the use of sodium hypochlorite for the early treatment of wounds before sepsis has developed will be found in the BRITISH MEDICAL JOURNAL, October 23rd, 1915, p. 609, and November 27th, 1915, p. 790.

December 16th, temperature 98.6° to 99.4°. December 17th, necrosed bone removed; much less pus. December 19th, temperature 99.2° to 99.4°. December 21st, almost all trace of pus disappeared, with wound surfaces clean. The counter opening was healing, and granulations were felt to be covering the bone surfaces.

CASE IV.

M. M. Rifle bullet wound of left leg. Very septic when received, October 29th, with iodine vesication and much inflammation. Hypochlorite was used twice daily. On November 2nd the wounds were clinically clean, and all inflammation and swelling had subsided.

CASE V.

A. W. O. Compound comminuted fracture of right ulna in upper third. When received on board, the wound had been thoroughly opened up, but was extremely septic, with much inflammatory oedema of the part. The superficial areas were dirty, and thick yellow malodorous pus drained out in large quantities. A large rubber tube was inserted, and surrounded with light gauze packing. Hypochlorite solution, 20 c.cm., was injected every two hours. Within a week the clinical appearance of the wound was absolutely healthy. The pus was replaced by a clear mucoid secretion, and the surfaces were covered with red healthy granulations. The swelling and oedema entirely disappeared, and the wound progress was most satisfactory.

CASE VI.

G. J. Rifle bullet wound of left arm above elbow-joint, involving the ulnar nerve and the external condyle of the humerus. An operation had been performed on shore before the patient was received. The bullet and fragments of bone had been removed, but the wound had been closed. Within a day of admission the arm was much swollen, and inflammatory oedema extended from the joint upwards. The forearm was much swollen also.

The wound was opened up, and a rubber tube inserted, passing to the site of the fracture. Hypochlorite, 20 c.cm., was given every two hours. The pus, which drained at first rapidly, changed to a mucoid secretion, and the inflammation and oedema rapidly diminished, and had disappeared at the end of five days. The tube was then removed and a simple dressing applied. The wound granulated perfectly, and at the end of ten days there remained only an area the size of a threepenny piece to be covered.

CASE VII.

A. B. Bomb wound of right leg. Received on board October 29th, three days after injury. Perforating wounds of calf, entry and exit 2½ in. apart; much pus present; temperature 104°. The wounds were incised; a pocket extending upwards was opened, and the whole freely irrigated with hypochlorite. The following day the temperature fell to 98° and did not subsequently rise above 99°. Three days later the wound was clean, with no discharge, and all swelling and inflammation had gone.

CASE VIII.

A. W. Bomb wounds of left leg received October 26th. Treated on board October 29th. Several severe wounds, all septic; one over external malleolus, penetrating the bone; a second on dorsum of foot, midway between two malleoli; a third in the middle of the leg, between the tibia and tibialis anticus muscle; and a fourth below and behind the head of the fibula.

The wounds were very dirty, but when opened up fragments of bomb were only found in the fourth wound. Hypochlorite dressings and injections by tube were used freely. After three days all the wounds appeared clean with the exception of the wound in the dorsum of the foot, where there was some cellulitis. It was explored, and a small pocket opened and emptied of pus. A tube introducing hypochlorite was inserted, after which marked improvement took place until the patient was discharged.

CASE IX.

A. H. Shrapnel wound of left leg received October 26th. Compound comminuted fracture of tibia in the lower third. The patient had been operated on ashore, and was received on board October 30th. The dressings were stinking, and the surface of the wound extremely dirty. Free irrigation with hypochlorite and subsequent injections were employed. The wound was far from being in a satisfactory condition when this case was discharged three days later, but, considering the state of the wound on admission, the improvement was really wonderful.

CASE X.

D. M. Perforating bullet wound entering right malar bone and emerging just below the angle of the jaw, causing a large neck wound, and plunging up the surface of the trapezius muscle for 3 in. at a depth of 1 in. Temperature on admission 104°. The wounds were cleaned, dressed with gauze soaked with hypochlorite, and carrying tubes for its renewal. On discharge, five days later, the temperature was normal and the wounds in the cheek and trapezius muscle were clean. The wound in the neck was suppurating slightly with some inflammation of the submaxillary gland.

CASE XI.

T. B. Compound comminuted fracture of right femur caused by shrapnel bullet. The wounds on the front and back of the thigh were freely incised, but no bone was removed. Rubber tubes were inserted to carry hypochlorite to the bottom of the wounds and the cavities lightly packed with gauze. The hypochlorite was renewed every two hours at first. The wound remained clean and did well.

CASE XII.

A. J. H. Shrapnel bullet wound over right frontal bone. Depressed fracture; trephine necessary when depressed bone removed with piece of bullet. Dura-uninjured. Temperature on admission 102°. On discharge, five days later, temperature was normal and the wound almost healed.

CASE XIII.

G. A. N. Compound fracture of left humerus, received October 26th. Musculo-spiral nerve exposed and partly divided. The whole track and wounds of entry and exit were very foul and stinking, with redness and oedema of the whole upper arm, when the case was received on board on the 29th. The wounds were enlarged, drained, and irrigated four-hourly with hypochlorite. No spread of sepsis occurred and redness and oedema rapidly subsided, as did the offensive odour. When discharged, four days later, the wound was lined with healthy granulations and there was only a trifling discharge of pus.

CASE XIV.

G. T. Compound fracture of jaw and shell wound of right arm. The fragment of shell had entered at the tip of the right shoulder and emerged above the external condyle of the humerus. All the wounds were horribly offensive. They were irrigated with hypochlorite under anaesthesia, and many loose fragments of jaw and detached teeth were removed. Four-hourly irrigation with hypochlorite was adopted, and the patient was given a chloramine mouth wash. On discharge, four days later, the patient's mouth was remarkably clean, but the external jaw wound was still discharging though relatively clean in appearance. Sloughs had all separated. The arm wounds were clean and lined by healthy granulations.

CASE XV.

W. C. When received on board the right foot was gangrenous as regards the soft tissues up to the base of the metatarsals; its appearance was black with an intense zone of inflammation of the higher part of the foot. The left foot was gangrenous to the base of the proximal phalanges, with similar signs of intense inflammation. The odour was appalling. Hypochlorite baths were used and at once removed the odour. In two or three days the dead soft tissues had softened and could be quite easily removed. The wounds took on a healthy aspect, and the granulations were red and clean.

CONCLUSIONS.

The advantages we have observed in the employment of the sodium hypochlorite solution in the treatment of septic wounds may be briefly stated as follows:

1. The simplicity and cheapness of preparation of the antiseptic.
2. Being non-toxic and non-irritating to the tissues when properly prepared according to Dakin's formula, the hypochlorite solution may be safely used in large quantities over long periods of time without ill effects.
3. The deodorant action of the solution is remarkable. The fetor from gangrenous tissues usually disappears in twenty-four hours.
4. The rapidity with which sloughs separate and clean granulation tissue is formed in a wound under its influence.
5. The infrequency of redressing required by cases treated as described with hypochlorite, compared with the constant change of dressings required in large wounds with other forms of antiseptic.
6. The fact that injections of the hypochlorite solution into the rubber tubes used in the dressings may with safety be entrusted to very imperfectly trained orderlies without fear of ill results, once the case has been adequately dealt with by the surgeon.

The facts referred to under (5) and (6) are very important considerations in war surgery, as cases frequently arrive in large numbers at varying intervals.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TYPHOID PERFORATION: OPERATION:
RECOVERY.

THE following case of perforation in a man suffering from unsuspected typhoid (no doubt modified by inoculation) is, I think, of interest as emphasizing the importance at the present time of a strict investigation into all cases of pyrexia, even when unaccompanied by other marked symptoms. It is also worth recording from a surgical point of view, since recovery took place in spite of the fact that operative measures were unfortunately not taken until some eighteen hours after the accident.

Pte. C. was admitted to the Reading War Hospital on

September 17th, 1915, having been wounded in Gallipoli on August 24th. On admission he had a small healed entrance wound in the buttock and an irregular open wound, about an inch in diameter, on the inner aspect of the thigh, where the bullet had emerged. He appeared in good health. He stated that he had been inoculated against typhoid in November and December of the previous year (two inoculations).

On September 28th it was noted that there had been some pyrexia since he had been in hospital, the temperature ranging from 100° to rather over 101°, though frequently down in the morning to normal. The man said that he felt perfectly well except that now and again he suffered from headache. His bowels had on several occasions been somewhat relaxed. No abnormal physical signs could be detected in chest or abdomen, and the tongue was clean. The pulse had varied with the temperature from 90 to 112. The wound had nearly healed.

On arrival at the hospital on the morning of October 1st I was informed that the patient had complained the previous afternoon of sudden severe pain in his stomach, and now appeared to have serious abdominal mischief. I found him with a temperature of 103.4°, a pulse of 136, and all the signs of an acute abdomen.

He was at once taken to the theatre and laparotomy performed. There was general peritonitis, with a quantity of free pus; the lower part of the ileum was covered with masses of lymph, and a perforation a quarter of an inch across, evidently the result of typhoid ulceration, was present in this portion of the bowel. I closed the hole with some difficulty, on account of the condition of the gut, and drained by means of a large tube passed down into the pelvis. The usual after-treatment for general peritonitis was adopted, and the patient made an excellent recovery, the only trouble being some suppuration in each breast where he had received subcutaneous saline infusion. He had fairly typical typhoid stools for about ten days after the operation, but by October 19th the temperature was normal. There was a short relapse from October 31st to November 11th. The patient is now (December) nearly well.

Bacteriological examination of the stools shortly after the operation showed the presence of a non-lactose fermenting bacillus, typhoid or paratyphoid (the exact identity not determined). On November 7th it was found that the blood agglutinated *B. typhosus* up to 1 in 500 dilution, but had no effect on *B. paratyphosus* A or B.

W. BERNARD SECRETAN, M.B., F.R.C.S.

A SECOND CASE OF COMPLETE INVERSION
OF UTERUS.

Mrs. R., aged 30, was confined early in September. She looked very delicate and fragile, and the pains were weak from inertia of the uterus. A little chloroform was given, and the delivery was very easily effected by forceps. The placenta caused no trouble, and the uterus contracted normally. All went on well for fourteen days. The nurse then assisted the patient to stool, when on pressure a pain was felt, and "something seemed to come down." On my arrival I found the fundus uteri well outside the vulva and still being extruded; there was no bleeding. An hour later Dr. MacLagan gave chloroform, and reduction was accomplished after some patient work in ten minutes or less. As in my previous case (BRITISH MEDICAL JOURNAL, 1910, vol. i, p. 260), the method by direct pressure on the fundus was not successful and was not long persevered with, whereas the other method was very readily effective. I reduced the bulk of the tumour into the vagina followed by the right hand, grasped the neck of the mass with the finger tips surrounding, and worked at it exactly as one would reduce a hernia. The patient made a good recovery. I venture to record this case on account of its very great rarity, and, after my experience, would suggest to any one who may be unfortunate enough to encounter this formidable accident that the method I have attempted to describe will most readily be successful.

C. L. FRASER, F.R.C.P., F.R.C.S. Ed.

Berwick-upon-Tweed.

DR. CHARLES RICHET, professor of physiology in the University of Paris, who is now serving in Russia, has been elected an honorary member of the University of Moscow.

Reports of Societies.

GUNSHOT WOUNDS OF THE CHEST.

At a meeting of the Medical Society of London, on Monday, January 17th, the President, Dr. W. PASTEUR, being in the chair, a discussion took place on gunshot wounds of the chest.

Colonel Sir J. ROSE BRADFORD, who opened the discussion, said that the material from which his paper was constructed was provided by the base hospitals in France from October, 1914, to the present time. Many hundred cases had been seen, several of which were very severe. Some had arrived at the base hospitals within two or three days after the injury, but the interval was usually longer. Some had been seen at the casualty clearing stations within twenty-four hours. The cases had been studied in collaboration with Major T. R. ELLIOTT and Captain Hubert Henry. Sir J. Rose Bradford said that haemothorax might follow a wound in some part other than the chest, such as one of the arm or neck. In these circumstances the chest condition might be overlooked, and mistakes might easily arise. Among the results which might follow gunshot wounds of the chest were haemoptysis, haemothorax, pleurisy, empyema, and pneumothorax. Haemoptysis might be a consequence of infarction after bruising, when there was therefore no proof that the missile had penetrated the lung. The haemothorax was not different from the ordinary variety of the condition, but was frequently infected. The pleurisy was often streptococcal, and frequently progressed to empyema. Pneumothorax was not infrequently accompanied by a large opening in the chest. When a large gaping wound was found in the lower half of the chest the lung was often clearly visible, and was not often completely collapsed. Despite the severity of the injury such cases might progress very favourably. When the wound occurred in the upper part of the chest a counter-opening was usually necessary.

He then considered the subject of penetrating wounds of the chest and lung. Haemothorax and even pneumothorax might be found on the side opposite to the wound in the chest. Such cases were often very puzzling at first. Sometimes a bilateral haemothorax was encountered when the bullet penetrated the thorax transversely. This occurrence was not uncommon with or without the lodgement of the missile. The pericardium was occasionally wounded, and recovery might even occur after so severe a result as haemopericardium. Surgical emphysema often accompanied haemothorax; it was usually limited, but was occasionally very extensive, and in one case had been general. The peculiar percussion note which it produced might suggest the presence of pneumothorax, and the sharp crepitations heard over it might cause it to be confounded with pleurisy. The haemothorax was infected in 25 per cent. of the cases.

Sterile Haemothorax.

The degree of collapse of the lung in sterile haemothorax varied with the amount of haemorrhage. In many cases the lower or middle lobes were collapsed, whilst the upper lobe was over-distended to an extreme degree, and floated on the upper surface of the blood. This was a very characteristic feature. The bloody fluid in the pleura was really defibrinated blood containing in some cases an added exudate from the pleura. The method which had been recommended for determining the degree of dilution of the blood by the number of red blood corpuscles he considered quite misleading, for it took no account of the number bound up in the clot. Regarding the advent of clotting, it had certainly taken place by the fourth day, and probably much earlier.

Symptoms.—Dealing with the symptoms, he spoke of the distressing cough and anxiety in the early stages. Haemoptysis occurred in a large proportion of the cases. It was sometimes deferred for three or four days, probably when due to bruising, and there was therefore an early and a late variety of this symptom. It was very seldom fatal; he had only met with one example of death from it in well over 1,000 cases. Cough was usually very troublesome. Dyspnoea was slight after the onset. Very slight icterus might occur after the first week, but not to such an extent as after haemorrhage into the peritoneal cavity.

Usually a slight fever was detectable, but this was as high as 103° or 104° F. only in exceptional cases. According to the temperature three groups of cases were recognizable: (1) Those in which the temperature fell immediately after paracentesis; (2) those in which it did not fall in this way although no infection was present, but fell slowly after two or three weeks—such cases were not very common; (3) those in which a sudden pyrexia appeared after two or three weeks and disappeared after paracentesis; these cases were exceptional.

Physical Signs.—The signs were not those merely of pleural effusion. At first there was a remarkable absence of definite signs; the percussion note might be only slightly impaired, and numerous râles and rhonchi might be heard. Twenty-four hours later most obvious signs might appear. The degree of displacement of the heart was not dependent upon the amount of effusion. The area of skodaic resonance above might be very marked. The breath sounds might be tubular or even amphoric and bronchophony and pectoriloquy were frequent. The diaphragm on the affected side was extraordinarily high, and it was not unusual for the stomach resonance to merge into the skodaic resonance above. Points of distinction from pleural effusion were the tubular breathing, bronchophony and pectoriloquy, and the more marked skodaic resonance. The heart's apex beat often underwent a peculiar change in position. It might at first be displaced considerably and then return towards the normal position in a day or so. Retraction of the affected side might be rapid if aspiration were not performed, and was more marked than in pleural effusion. Collapse of the lung played a greater part in the development of physical signs than it did in pleural effusion. The presence of vocal fremitus did not exclude haemothorax. In one group of cases the signs resembled those of massive collapse of the lung, and cleared up in a few days except at the extreme base, where was situated a small haemothorax.

Diagnosis.—A common error, he said, was to confuse haemothorax with pneumonia, and to label the case "traumatic pneumonia." Pneumonic consolidation on the side of the lesion, he thought, must be extremely rare. Another distinction which had to be made was between haemothorax and pneumothorax or pneumohaemothorax. The position of the apex beat was of considerable service. As to the determination of the size of the effusion, it appeared that 2 or 3 pints usually caused dullness as high as the middle of the scapula. The presence of infection of the haemothorax could only be determined accurately by a bacteriological examination of the fluid, but it might be inferred by the general state of the patient and his degree of illness and of pyrexia.

Treatment had at first been by the expectant method, but although the patients did well the condition was protracted and they ailed for some time. With the employment of aspiration combined with oxygen replacement, the lung rapidly re-expanded and the pyrexia quickly subsided. The collapse soon cleared up, and the period of invalidism was measured by weeks rather than by months as before. This treatment was very successful, and no case of secondary haemorrhage occurred. Indeed, secondary haemorrhage was only met with in one case, and in that instance aspiration had not been used. No re-accumulation of fluid followed.

Infected Haemothorax.

Infection occurred in 25 per cent. of the cases; it arose from the lung in 20 per cent., and from the exterior in 80 per cent. In such cases removal to the base was advisable towards the end of the first week, otherwise valuable time was lost. Only by an examination after exploratory puncture could a definite diagnosis be made. Sometimes the patients were very ill, but this was not always true at first. With anaerobic infections symptoms closely simulating haemorrhage occurred, and also with this infection a cracked-pot note was obtainable by percussion. Cases with streptococcal infection were usually very seriously ill, and contralateral pleurisy was more commonly met with.

Pneumothorax.

He spoke very briefly of pneumothorax. It was very uncommon in this connexion in his experience. Only 12 examples were diagnosed in nearly 500 cases, and its

presence was proved in only 4. It was almost always right-sided, perhaps because the left-sided cases were fatal before the patients were transferred to the base. He thought that good results had been obtained by aspirating the air-containing space first, and opening the pleura afterwards, when the lung had partly expanded.

Pathology and Bacteriology.

Captain H. HENRY, R.A.M.C., spoke of the pathology and bacteriology. He said that his data had been derived from three sources: (1) *Post-mortem* examinations in 100 cases; (2) routine laboratory examinations of the fluids removed, and (3) experiments upon animals. It had to be remembered that his investigations concerned a particular group of cases—those which arrived at the base hospitals. In 6 of the fatal cases death was due to injury to the vertebrae and spinal cord only. Of the remaining 94, 78 had haemothorax and 16 had not. In only 8 at most of the cases with haemothorax was death due to simple bleeding; the remaining 70 were complicated—26 cases by damage to viscera, and 44 by sepsis. Captain Henry then described the typical *post-mortem* appearances of fatal cases of haemothorax. He said that primary coagulation of the effused blood and a deposition of fibrin occurred in a few hours. Afterwards exudation followed, which induced secondary clotting. The lung submerged in the extravasated blood collapsed; the stages of this collapse were more rapid and its degree more complete than occurred with pleural effusion. The unsubmerged part of the lung was voluminous from the high grade emphysema which affected it. The line of demarcation between the haemothorax below and the emphysema above varied greatly in obliquity. The shifting over of the mediastinum and its contents was due at first to the collection of blood, but later to inflammatory change after it had become encysted. In septic haemothorax, the pleura and lung became covered by a secondary generation of fibrin, which, moreover, might spread throughout the pool of blood. In anaerobic infection the haemothorax often had a foul odour, but this was not constant. Sometimes there was little evidence of infection in the haemothorax itself, and search had to be made further afield, as on the pericardium, etc., to reveal it. The naked-eye appearances of the fluid were no guide as to the presence of sepsis, nor was the nature of the cellular constituents. Anaerobic organisms and streptococci accounted for the great majority of the infections.

Experiences in England.

Lieutenant-Colonel W. HALE WHITE said that in his experience if the patients were well enough to be sent to England they usually progressed favourably. He had seen some fifty, none of which ended fatally. In a large number of cases of bullet wounds of the chest the patients suffered little from their effects. The dyspnoea seen in many cases was altogether out of proportion to the physical signs. He thought that in some cases it was at least partly "functional" in origin. Haemoptysis was an uncommon symptom of the condition as seen in this country. It had not recurred except in one case. He had been struck by the fact that after the fluid had been aspirated in haemothorax the heart did not return to its normal position. It was difficult to give an opinion as to when aspiration should be performed; he thought that certainly every case in which the fluid amounted to over 20 oz. should be so treated. A point which was often forgotten was that the chief trouble was connected with the collapsed lung, and the patient was not instructed as to the manner by which it could be re-expanded. It was a question whether this should be by breathing exercises or by short walks uphill.

Dr. MURRAY LESLIE thought a great advance had been made in the attitude adopted towards aspiration in haemothorax. It was very different from that which was in vogue during the South African war. He endorsed Colonel Hale White's remarks as to the importance of breathing exercises or walking uphill to re-expand the lung.

Mr. CORTLANDT MACMAHON, in describing exercises suitable for such cases, said that the main objects were: (a) To prevent pleural adhesions forming, and to break down existing adhesions by careful and gradual movements; (b) to enable lungs which had collapsed to regain

their normal condition; (c) to reduce haemothorax and pneumothorax; (d) to restore the normal shape of the chest walls, which had fallen in owing to collapse of the lungs; (e) to assist the discharge of pus by increasing lung inflation; (f) to improve the general condition by the tonic effects of the exercises, and especially to overcome breathlessness on exertion. The procedure on which he laid greatest stress was that the body should be bent laterally away from the side of the injured lung; the uninjured lung being thereby partially collapsed, the lung on the injured side was made to inflate more definitely. To help this inflation a pressure of 30 lb., increased to 60 lb., was put upon the uninjured side by the operator's hands and the abdomen made to contract with the breath held.

Dr. F. J. POYNTON referred to cases of wound of the chest with, perhaps, some fever, the cause of the illness being obscure. He spoke of the importance of not being in a hurry in such cases to resort to surgical treatment. Caution was an important factor in the treatment of such chronic cases, which often cleared up with a little patience.

Captain MORRISTON DAVIES, R.A.M.C.T., also spoke.

THE SOLDIER'S HEART.

At a meeting of the Section of Pharmacology and Therapeutics of the Royal Society of Medicine held on January 18th, the President, Lieutenant-Colonel W. HALE WHITE, being in the chair, Sir JAMES MACKENZIE opened a discussion on the soldier's heart. His paper, and that of Dr. McN. WILSON who followed, are published at pages 117 and 119.

Dr. POYNTON thought that at present a broad view was the most helpful. He pictured a group of symptoms predominantly cardiac, prone to arise in presumably healthy men at a vigorous time of life under the exigencies of military service. He thought the causation was complex, and would consider the following points: (1) Latent infection; (2) the cases which seemed to him classical; (3) the importance of prevention; (4) nerve shock and strain, and the possibilities of recovery; (5) hyperthyroidism; (6) heat-stroke.

1. *Latent Infection.*—This view had been again insisted upon in a recent memorandum by Drs. Cotton, Lewis, and Thiele, describing the discovery of streptococci and staphylococci in the urine of such cases. As indirect support, he would state that a streptococcus obtained from acute rheumatic cases could experimentally produce cardiac failure, with or without notable dilatation, and from the urine of these animals the streptococcus could be recovered. In man also there was a group of rheumatic cardiac cases in which, without endocarditis or pericarditis, the heart wall was weakened, and his study of them led him to see in such many of the symptoms observed in soldier's heart. It was clear, if the suggestion of these writers was established, that to the already well-known causes of latent infection there would be added an important group which for the moment he would term "septic."

2. Nevertheless, latent infection did not appeal to him as furnishing the really classical examples; these he had seen, during the ten years preceding the war, in privates in the Guards regiments. They were adolescents of great stature and with big frames, usually a little anaemic. The symptoms commenced early in their training. At first there was great fatigue at the end of the day; then thumping of the heart at night occurred, then dyspnoea and palpitation on exertion, finally a "fall out" on march, dead beat, or a sudden syncope with or without slight convulsion. The thumping, ineffectual heart beat was very evident in these cases. He did not believe that latent infection was a factor, though he could not prove this. He looked upon the cardiac weakness as either congenital or much more frequently acquired. The large unconsolidated frames had outstripped the cardiac development. Strain was produced by limited diaphragmatic excursion and hard physical exertion carried on with needful routine. Tobacco and possibly beer were adjuncts. Indigestion was frequent and nervous symptoms were soon superadded.

3. The importance of the possibility of latent infection at present was very great. We had a large number of

convalescent cases of dysentery, enteric, and other infections now, and presumably they might form the nucleus of an army of "soldiers' hearts." Fortunately, an unforeseen remedy had appeared. These infectious cases required elaborate tests, and the time taken over them gave us splendid opportunities for controlling these most rash of convalescents until they had shaken off their weakness, and braced their potential "soldiers' hearts." The lines of treatment, if infection was made the predominant factor, were clear, and were preventive—namely, (a) accurate histories; (b) treatment of obvious foci of infection in tonsils, teeth, etc.; (c) patience in the convalescent stage of infections. When a case was in the broken-down stage, rest and a progressive forward policy in exercise were essential. His opinion was that a man with a severe breakdown, though eventually recovering, would not see active service again in this war. For what he called classical cases he would again from his experience emphasize prevention. Were we careful enough of young, overgrown recruits? Barrack life could not be converted into a preparatory school, but he would venture to submit that some tactful form of supervision on routine lines would be valuable. When symptoms occurred he took an unfavourable view of severe examples of this group, and believed they would not make soldiers.

4. *Nerve Shock and Strain.*—He looked upon the heart as so intimately connected with the nervous system that in considering heart strain he could not clearly differentiate the muscular and nervous symptoms. In this group he put nerve first, muscle second; in the preceding, muscle first, nerve second, but both were involved. He had seen striking cases from shell shock, and should like to hear what the section thought of their prognosis. One case of his bore on this. An officer at Ypres developed, after shell shock, these cardiac symptoms, and was treated, with progressive improvement, by the speaker for some months. Eventually, without his knowledge, the officer returned ten months later, and in his first heavy fighting collapsed at once with all his old symptoms aggravated. Dr. Poynton's views on their treatment mostly coincided with those of previous speakers. "Short of fatigue" was the keynote to exercise, but he did not, except from the point of view of research, favour the grouping together of these cases either in wards or in convalescent homes.

5. He attached importance to the suggestion of hyperthyroidism, seeing that it introduced a new line of treatment in the shape of x rays, but he wished to learn the right perspective, for his personal experience was against the frequency of this explanation, though he was absolutely open to conviction.

6. Lastly, heat-stroke was an obstinate and difficult factor in some of these cases, and in his opinion their outlook unfavourable. In the group due to nerve shock and strain, a cheery doctor, a minimum of complete rest, cheerful companionship, with pleasing exercise short of fatigue, and time, were his mainstays. Drugs which corrected dyspepsia, and were gently soothing to the nervous system, were useful.

Dr. R. W. MITCHELL said that when the soldiers suffering from heart symptoms were removed from the front he had found that the cases of right ventricular failure settled down, whilst those with the "irritable heart" did not. He could corroborate the occurrence of an intense feeling of suffocation. It was very real and accompanied by change in the patient's colour and shrinking of the skin, and was followed often by the passing of a large quantity of urine, even as much as two quarts at once. There was often tenderness with a dilated heart, but none with the "irritable heart." The patient became very sensitive to the action of his own heart. The first result of exercises was to fix the chest, not to expand it, and a stage was soon reached in which the chest became immobile and the respirations were entirely abdominal. Dr. Mitchell thought that this limited movement of the chest was connected with the production of an irritable heart. As, in spite of the great stress and mental strain of work in the trenches, comparatively few soldiers developed heart affection, he did not attach much importance to these factors. He believed, however, in the influence of poisons and of exhaustion.

Dr. P. HAMILL thought the condition described by Sir James Mackenzie a very definite one. Most cases could

be traced back to some undue exertion during some febrile disorder. The proportion of cases in which a history of antecedent diarrhoea could be obtained was very large. Electrocardiograms failed to demonstrate any primary heart disorder. Any little excitement caused such hearts to beat at a rapid pace. The condition was very liable to relapse. As to the treatment by moderate exercise, fresh air, and pleasurable surroundings, he quite agreed with Sir James Mackenzie. Briefly, the heart was strained whilst in a partly poisoned condition, but a psychological factor in the causation must not be lost sight of. The severely affected hearts were probably damaged permanently, but whether this were so it was for the next generation to decide.

Dr. ALEXANDER MORISON said that he was entirely in accord with Sir J. Mackenzie as to the methods by which such cases should be treated. There was nothing amiss with the size, rhythm, or mechanism of the heart, yet the patients were incapable of the usual amount of exertion. It occurred among the young and those of a neurotic type. Any disturbance which arose was attributable to the nervous system; there was no evidence of primary cardiac disorder. The utmost caution was required in attempting to foretell what would happen to such cases. He thought that the chances of such patients being afterwards of use as soldiers were negligible.

Dr. O. LEYTON thought it possible to distinguish cases in which the heart muscle was affected from those in which the vasomotor system was chiefly at fault, by noting the ratio of intensity between the basal and apical sounds. In cases in which the heart muscle was much affected by toxic causes he had noted a difference in the ratio from the normal. In others, complex in origin, when the vasomotor system was at fault, there was no change in this ratio.

Dr. FLORENCE STONEY thought that the associated signs showed that "irritable heart" was one of the symptoms of Graves's disease. The activity of the thyroid gland could be regulated to any required extent by x rays, and the condition could thereby be cured. A tendency to thyroid derangement occurred in families, and this derangement followed on the overstrain and toxic influences to which these patients were subjected. It was important at the commencement of treatment to give attention to the possible influence of pyorrhoea. The improvement obtained by x-ray treatment was slow in some cases, but astonishing in others.

Dr. T. R. BRADSHAW said that in not a single case which he had seen at the Western General Hospital among soldiers who had been sent back as suffering from valvular disease of the heart had he detected a murmur. It was unfortunate that the diagnosis of valvular disease should be made if there was any doubt, for when known to the individual it affected his whole career. The questions of importance were whether these men would again become efficient soldiers or become fit for home service. If there was no prospect of their returning to duty they should be invalided out of the service.

Dr. BEZLY THORNE said that the condition was not confined to soldiers, but was met with commonly in civilian practice among children and adolescents, and it sometimes persisted until middle life. He had ventured to name it cardio-vascular atony. He believed that the cause was toxic in the great majority of cases, but the patients could be made well without bacteriological treatment. A difference which he had noticed in the condition as it occurred amongst soldiers who returned from the trenches was that they showed more fibrillary tremor of the fingers and were more jerky. He considered the Nauheim treatment, especially the baths, valuable; in about two months in every case the patient was restored to permanently good health.

PROFESSOR GIUSEPPE SANARELLI, the distinguished Italian hygienist, has been appointed editor of the *Avenire Sanitario*, a journal which has done good work in the promotion of sanitary reform and in the defence of the interests of the medical profession.

COUNT DELLA SOMAGLIA, president of the Italian Red Cross, has set up a central propaganda committee in Rome to make known to the public what it is doing in the war, and enlisting active sympathy and co-operation in the work. Affiliated committees have been formed in the principal cities of Italy.

Rebueluz.

RADIUM AND X RAYS.

COLWELL and SIDNEY RUSS, in publishing a book on *Radium, X Rays, and the Living Cell*,¹ state that their object is to describe some of the main experimental facts which have been established as to the effects of the α rays and the rays from radium upon living cells. When innumerable papers are appearing day by day in medical journals all over the world (a few scientific, but by far the larger proportion merely personal records of cases and results), it is well to have a clear and lucid account of the chemical and physical properties of these radiations, and a rational exposition of their effects on living cells, with a scientific explanation of the manner in which these effects are brought about. With these objects in view the authors have produced a work which should do a great deal towards placing α ray and radium therapeutics on a more scientific basis than has hitherto been possible. In the first chapter an important point is emphasized in dealing with the measurement of α rays, a point which is by no means commonly known even amongst so-called experts. The change of colour in a prepared pastille is a common method of measuring an α -ray dose, and yet by a simple experiment this method can be shown to be very inaccurate. The authors point out that a "soft" tube in a certain time will change the pastille to the standard tint; then harden the tube, readjust the primary current, and a new pastille suffers the same colour change in the same time. The dose, as measured by the two pastilles, is the same, yet the clinical effects upon the tissues, seeing that the tube condition is quite different in the two cases, must be profoundly different. The early chapters on α rays, secondary α rays, the transmission of α rays through matter, the ionization effects, and other similar matters should be of great value to α -ray therapeutists. They are followed by chapters on the radio-active substances and their emanations, written on similar lines. Dealing with the standard of radio-active quantity, it is pointed out that the maché unit has been much abused by its too general use, and that its use for cases other than that for which it was originally intended—namely, the measurement of very small quantities of emanation in waters—is to be deprecated. Part II starts by describing the chemical action of radium and of α rays, and then follow chapters on the effect upon certain low forms of animal life. The diagrams showing the restriction of development following radium irradiation of the ova of triton are remarkable; a description of the histological examination of a human fetus after exposure to α rays is of great interest. Next we have the results of experiments on the growth of plants and of bacteria, and note that the authors have omitted to refer to the experiments carried out by Abbe. The latter part of the book, well illustrated by reproductions of photomicrographs, deals with the histological changes brought about in various organs, such as the skin, the blood and the blood vessels, the various glandular structures, the nervous system, and other tissues. A full account of the changes in malignant cells follows, and emphasis is laid on the fact that the administration of the type and intensity of the radiation most appropriate to any particular growth is a matter of great difficulty. The data may at present be insufficient for any sure basis of radio-therapy, yet a large number of facts are being gleaned which should render this possible in the near future. Short chapters on the production of malignant disease by the rays, idiosyncrasy and dosage, the physiological effects, and the selective and differential action of rays, form the concluding part of the work. Two features add to the value of the book—namely, that a very complete bibliography follows each chapter, and that the authors in each section have placed side by side the chapters on radium and α rays. This method of arrangement makes it easy to follow and to compare results, and adds greatly to the value of the book for reference.

Many textbooks, large and small, have been published on radiography during the past twenty years. It is not

saying too much in praise of Dr. ROBERT KNOX's book, entitled *Radiography, X-Ray Therapeutics, and Radium Therapy*,² to describe it as being the best which has as yet been published on these subjects in the English language. The first part deals with α -ray diagnosis; the chapter on instrumentation and technique is very complete, and if any criticism is to be made on the general scope of the book, it would be that perhaps too much space has been allotted to this part of the subject. The whole field of α -ray diagnosis is admirably dealt with, and there are singularly few, and these somewhat unimportant, omissions. For the student the very clear description of diagnostic possibilities will be very valuable, and the short descriptions of methods and technique which precede each chapter add to the value from this point of view. The chapters which describe the application of the method to the thorax, the stomach, and the kidneys are of special merit. The illustrations of this division of the book are very good. A feature of them and an innovation in α -ray illustration, is that side by side are shown reproductions of the plate and the print from the plate, of the same radiographs. The artistic merit of the reproductions is very high, and this double method of showing α rays is of value as a help to learning to read α -ray pictures. A further good point is that common and everyday radiographs are reproduced, and not those of rare and unusual conditions. The chapter on the localization of foreign bodies is well and clearly written. It deals with the simple and more useful methods, but this part of the book, owing to the importance the subject has at the present time, might with advantage have been extended. Part II, which deals with α -ray and radium therapy, is practical, and whilst describing the scope of treatment in a large number of diseases, is restrained and critical as regards results. This part of the subject is well illustrated by photomicrographs of pathological interest, and numerous photographs of cases before and after treatment. The concluding portion, on radium physics, written by Phillips, is altogether admirable, as it possesses the two great merits of lucid description and simple language. The medical practitioner will find this a useful book of reference, and the beginner in α -ray work a valuable textbook.

NEUROLOGY.

THE first edition of CHURCH and PETERSON's well-known American textbook of *Nervous and Mental Diseases*³ came out in 1899. The eighth edition, now before us, preserves the character of the previous editions, and has been brought up to date by what the authors describe as "one hundred and fourteen sizable interpolations" and over two hundred minor alterations. The first 626 pages of the book are by Dr. Church and give an account of nervous diseases divided into eight sections. In one of these, headed "Diseases of the Nervous System without known Nervous Anatomical Basis," are included a number of pathological conditions, such as myxoedema, exophthalmic goitre, tetany, and various forms of dyspituitarism, that are now generally recognized to be disorders connected with abnormalities in glands with internal secretions. This section also contains a chapter on what Dr. Church calls the "Infection Neuroses"—namely, tetanus, hydrophobia, and chorea—which are said to be "not marked by known changes in the neural apparatus." Such views may perhaps be characterized as unduly conservative and in need of revision. In his account of the bacteriology of chorea (p. 561) Dr. Church gives only four references to the literature of the subject, the latest dated 1899. At the end of the volume Dr. Peterson gives an account of mental diseases extending to 230 pages, clearly written, concise, and well arranged. The book is well printed, the illustrations are good, and there is an adequate index at the end of the volume. It is well written, not unduly abstruse or scientific, and devotes a good deal of space to the important subject of treatment throughout. It may be recommended to medical practitioners and students who are in search of a sound practical textbook of diseases of the nervous system.

² *Radiography, X-Ray Therapeutics, and Radium Therapy*. By R. Knox, M.D. Edin., M.R.C.S. Eng., L.R.C.P. Lond. The Edinburgh Medical Series, General Editor, J. D. Comrie, M.A., B.Sc., M.D., F.R.C.P.E. London: A. and C. Black, Ltd. 1915. (Roy. 8vo, pp. 426; 64 plates, 245 figures. 25s. net.)

³ *Nervous and Mental Diseases*. By A. Church, M.D., and F. Peterson, M.D. Eighth edition, thoroughly revised. Philadelphia and London: W. B. Saunders Co. 1914. (Roy. 8vo, pp. 940; 338 figures. 21s. net.)

¹ *Radium, X Rays, and the Living Cell*. By H. A. Colwell, M.B. Lond., D.P.H. Oxford, and S. Russ, D.Sc. Lond. London: G. Bell and Sons, Ltd. 1915. (Med. 8vo, pp. 334; 61 figures, 2 plates. 12s. 6d. net.)

Dr. CAMPBELL THOMSON's book on *Diseases of the Nervous System*,⁴ now in its second edition, gives a clear and fairly brief account of the subject that should be of great utility to the medical student. The subject matter is divided into six sections, of which the last, dealing with diseases of the brain and diseases of general origin, occupies nearly half the book, and illustrates the fact that the classification of the diseases called nervous is far from having reached finality. Dr. Thomson writes clearly and concisely, and the illustrations, many of them taken from cases in his own practice, serve excellently to illuminate the points at issue. The text is well up to date, and there is a good index. We can recommend the work to practitioners and students of medicine who are in search of a sound and tolerably short manual of nervous disorders.

Six years ago a review of the excellent textbook of nervous diseases edited by Dr. CURSCHMANN was published in the *BRITISH MEDICAL JOURNAL* (1909, ii, 987). The book was well up to date, complete from the point of view of the German literature of the subject, and well illustrated. An authorized English edition of the work, edited by Dr. C. W. BURR of Philadelphia, has now been issued.⁵ The translation has been done tolerably carefully, and has been lightened or diversified by the introduction of a number of American colloquialisms and slang terms. The text is not free from misprints, for example, "Tringeminus," on p. 23, should be "Trigeminus"; "polyneuritis psychosis," on p. 168, should be "polyneuritic psychosis"; on p. 481 "a diadocokinesis" should be "adiadocokinesis"; the oft-quoted names of "Wickmann" and "Déjérine" should be "Wickman" and "Dejerine." The German original contained 289 illustrations in the text; these have been cut down by Dr. Burr to 246, and appear with their German notation, where such notation is, in the English translation. Not a few of the blocks from which they have been printed seem to be unduly worn. It does not appear that anything has been done to bring the book, originally published in the summer of 1909, up to date. Even in the account of acute anterior poliomyelitis—a disease that has been so brilliantly investigated by Flexner and other American workers during the last few years—we look for a mention of Flexner's name in vain.

GUY'S HOSPITAL REPORTS.

THE editors of *Guy's Hospital Reports*⁶ inform the subscribers, in their preface, that though many of the articles in the present volume were already in print by August, 1914, their publication has been delayed, every member of the staff of Guy's Hospital having been so fully engaged with extra work arising directly or indirectly out of the needs of the sick and wounded, that little, if any, time has been available for the writing of papers or reports. Dr. Pembrey contributes an excellent article on the advantages of physical games over gymnastic work. He argues that there is a medicinal flavour in set exercises—some are called nutritive, others corrective, and others depletive—but most of them cause undue fatigue, lack interest, and are monotonous. On the other hand, resistance to disease is increased by the outdoor life associated with games, and in the long run it is cheaper to provide playing fields than gymnastic instructors. Dr. Pembrey admits that games may have one serious drawback, and that is when they are played for notoriety or gain, and not for pleasure. Mr. Higgins contributes an interesting and amusing paper on charlatans and "miracles." Drs. Eason and W. Johnson write on four cases of pituitary tumour, and the volume includes some other clinical and scientific contributions. We must congratulate Mr. C. H. Golding-Bird on his very complete obituary notice of Thomas Bryant, the last link that bound the modern school of

surgery in Guy's Hospital to that of Astley Cooper, Key, and Birkett. Beyond the limits of the Borough, Thomas Bryant was best known when in his prime for his textbook on surgery, much needed in the seventies, as Mr. Golding-Bird rightly reminds us.

NOTES ON BOOKS.

A THIRD edition of the popular little work by Sir PARDEY LUKIS and Lieutenant-Colonel BLACKHAM has appeared under the slightly changed title of *Tropical Hygiene for Residents in Tropical and Subtropical Climates*.⁷ The text has been carefully revised, enlarged, and brought up to date. Among the matter added are a full description of hookworm disease and its prevention, a dissertation on goat's milk and undulant fever, and two entirely new chapters—the first dealing with the sanitation of camps in the tropics, the second with hydrophobia. In their preface the authors state that the second edition was exhausted in less than a year. This, better than anything, speaks for the popularity of the work, and this edition, just as the previous one, can heartily be recommended.

Lieutenant-Colonel BIRDWOOD's laboratory manual for students of tropical medicine⁸ and practitioners in hot countries has now reached its second edition. It contains eighty-nine short chapters, each giving precise numbered directions how to carry out such operations as blood-staining, blood-counting, vaccine formation, examination of urine, and the like. It is based on the author's extensive experience in the teaching of Indian students, and appears to contain all that is required, in an easily assimilable form. The book is interleaved with plain paper, so that notes may be added as required. The first edition of the book was exhausted in a year; we wish the second an equally rapid and happy exit.

The address delivered at the University of Leeds Medical School on October 1st, 1915, by Sir WILLIAM OSLER, Bt., on *Science and War*, was noted in the *JOURNAL* for October 16th, 1915, p. 572. It has now been published in the form of a pamphlet⁹ by the Clarendon Press, and may be warmly commended to the attention of general and medical readers.

⁷ *Tropical Hygiene for Residents in Tropical and Subtropical Climates*. By the Honourable Surgeon-General Sir Pardey Lukis, K.C.S.I., V.D., and Lieutenant-Colonel R. J. Blackham, C.I.E., R.A.M.C. Third edition, revised and enlarged. Calcutta and Simla: Thacker, Spink, and Co. London: W. Thacker and Co. 1915. (Cr. 8vo, pp. 302; 52 figures. 4s. 6d.)

⁸ *Clinical Methods for Students in Tropical Medicine*. By G. T. Birdwood, M.A., M.D., D.P.H., Lieut.-Colonel I.M.S. Second edition. London: W. Thacker and Co. Calcutta: Thacker, Spink, and Co. 1915. (Pott 8vo, pp. 260. Rs. 2.8.)

⁹ *Science and War*. By Sir W. Osler, Bt., M.D., F.R.S. Oxford: The Clarendon Press. 1915. (Demy 8vo, pp. 39. 1s. 6d. net.)

MEDICAL AND SURGICAL APPLIANCES.

Plates for One-armed Men.

DR. A. E. SHIPLEY, Master of Christ's College, Cambridge, has devised a couple of plates for the use of soldiers and sailors who have lost an arm. One is a soup plate, with a depression in the centre, from which the last two or three spoonfuls of soup can easily be removed. The other is a plate for solid food, which has vertical sides and an overhanging rim; against this pieces of meat or pudding can be pushed without any risk of their toppling over the edge

FIG. 1.—Section of meat or pudding plate.

FIG. 2.—Section of soup plate.

of the plate. "For convenience of commerce," Dr. Shipley continues, "it has been suggested that the plates should be named, and 'Unimanus' has been suggested (Cf. *Livy* 35, 21 and 41, 21), but it seems simpler and certainly shorter to call them 'manchet' plates," *manchet* being the French word for a one-armed man. The plates are being made by Messrs. Goode, 16, South Audley Street, London, who are solely responsible financially and have consented to devote rather more than 20 per cent. of the profits to the Serbian Relief Fund.

⁴ *Diseases of the Nervous System*. By H. Campbell Thomson, M.D. Lond., F.R.C.P. Second edition, revised and enlarged. London: Cassell and Co., Ltd. 1915. (Cr. 8vo, pp. 570; 120 figures. 10s. 6d. net.)

⁵ *Text-book of Nervous Diseases*. Authorized English edition, edited by C. W. Burr, B.S., M.D. In two volumes. Philadelphia: P. Blakiston's Son and Co. 1915. (Roy. 8vo, pp. 1158; 246 figures. 12 dols. net.)

⁶ *Guy's Hospital Reports*. Edited by F. J. Steward, M.S., and Herbert French, M.D. Vol. lxxviii, being vol. liii of the Third Series. London: J. and A. Churchill. 1914. (Demy 8vo, pp. 223. Terms to subscribers, 6s.; to non-subscribers, 10s. 6d.)

MEDICAL REGISTRATIONS AND MEDICAL STUDENTS IN 1915.

WE referred briefly last week to some statistics issued by the President of the General Medical Council showing the number of medical practitioners whose names had been added to the *Medical Register* in 1915, and the number of medical students registered in the same year. The following is the detailed statement showing the number in each of the three kingdoms in 1915, and the annual average during the previous five years:

Medical Practitioners Registered.

	In 1915.	Annual Average during the Five Years 1910-14.
England	863*	591
Scotland	412	384
Ireland	251	197
Total	1,526	1,172

Medical Students Registered.

	In 1915.	Annual Average during the Five Years 1910-14.
England	754	620
Scotland	694	517
Ireland	470	304
Total	1,918	1,441

* This number includes 269 practitioners with colonial and foreign qualifications.

These statistics will give much food for thought, and we confess that at present their meaning is not clear.

The increase in registrations of practitioners is remarkable, in that after all deductions are made it is above the average. The increase in registrations in England is partly to be accounted for by the large number of practitioners registered with colonial and foreign qualifications. In 1914 the number was 77, this year it is 269. It would appear, therefore, that the number of English medical practitioners added to the *Register* by registration in England in 1915 was about 70 above the average during the five years 1910-14. In Scotland the number was 28 above the quinquennial average, and in Ireland 54. A large part of this excess is probably due to earlier qualification of fifth-year students anxious to join the R.A.M.C. The figures obtained from the medical schools by the President of the General Medical Council last year suggested that there was a shortage of from two to three hundred among fifth-year students. The policy adopted by the War Office, on the advice of the medical authorities, of requiring senior students who had enlisted in various capacities to return to their schools with the view of qualifying, is probably the chief cause that the expected shortage has disappeared and has been replaced by an actual increase. Altogether it may be estimated that, apart from practitioners registered with colonial and foreign qualifications, some 350 more practitioners were registered during 1915 than the figures furnished by the schools last year appeared to authorize us to expect. The return of the fourth-year student from the ranks will tell in the present year in a similar way. Pessimism, therefore, about the immediate future of the supply of medical men seems to be discounted.

With regard to the more distant future, matters are very much more uncertain. It is true that the number of medical students registered in 1915 is in all three countries in excess of the annual average during the five years 1910-14 (the total excess amounting to 477), but this increase has, we believe, occurred outside London, Cambridge, and Oxford. It is partly to be accounted for by the increase in the number of women students. Until the figures have been submitted to more detailed analysis it is impossible to say what proportion of the increase is thus to be explained, but probably the number of women students will not be found to exceed 200. This conclusion is perhaps confirmed by the increase in the numbers entering the Scottish, Irish, and northern English schools, which admit women students on the same terms as men. It seems safe to assume that the number of male entrants this year is at least 250 above the average for the five years before the war. In connexion with the preference shown for the northern schools, it may be noted that the Scottish student passes his preliminary examination

in general education on the average about a year earlier than the southern English student, so that there are more first-year students under military age than usual. Parents are probably becoming conscious that the medical profession offers better prospects in the future than hitherto, but as they have to study economy send their sons or daughters to the medical school which is nearest and also less expensive. At the same time the figures as to the number of medical students registered in 1915 are open to the fallacy that though these students have registered they either already belonged to an officers' training corps, or will join one; hence, as was the case last year and the year before, very many are receiving commissions, and are therefore withdrawn from the actual study of medicine.

ROYAL MEDICAL BENEVOLENT FUND.

(Continued from page 97.)

THE following is a continuation of the summary of cases relieved by the Committee at its meeting on December 14th, 1915:

Daughters, aged 64 and 66, of M.D.Leyden who practised in London and died in 1858. Applicants' only certain joint income £28, which they supplemented by taking in boarders. Owing to the war the boarders have entirely ceased and they are in difficulties. Helped by the Fund twenty-years ago. Voted £12 and the elder sister recommended for an annuity.

Widow, aged 63, of M.D.Dub. who practised at Cambridge and died in 1904. Applicant had managed to live by taking in resident pupils, but owing to the war has practically lost them all. Rent paid by relatives, but now in temporary difficulties, owing to the loss of above, and illness. Voted £10 and referred to two other organizations for help.

Widow, aged 58, of L.S.A.Lond. who practised at Bourne-mouth and died in 1913. Applicant was left totally unprovided for. Has a pension of £26 per annum from another society, and during the last year has only received £5 from lodgers. Health very unsatisfactory, and unable to let more rooms. Relieved once, £12. Voted £12 in twelve instalments.

Daughter, aged 53, of M.R.C.S.Eng. who practised in London and died in 1880. Applicant's health is very bad and she is quite unable to work. Lives with a widowed sister, who finds home but cannot do more. Relieved six times, £64. Voted £10 in two instalments.

Daughter, aged 58, of L.R.C.P.Lond. who practised at Brierley Hill and died in 1872. Applicant suffers from chronic ill health, and recently fractured her ankle. Only income an annuity of £35 from another charity, and a little help from friends. Relieved eight times, £53. Voted £12 in twelve instalments.

Widow, aged 54, of M.R.C.S.Eng. who practised at Yelverton and died in 1908. Applicant endeavours to make a living by taking in boarders, but does not get sufficient to make it pay. Relieved nine times, £107. Voted £12 in twelve instalments.

Widow, aged 42, of M.R.C.S.Eng. who practised in North Wales and died in 1910. Applicant was left quite unprovided for, with two children now aged 6 and 9 years. Has free rooms in return for services, and makes a little by selling goods on commission, but not sufficient to meet expenses. Relieved four times, £40. Voted £10 in two instalments.

M.R.C.S.Eng., L.R.C.P.Lond., aged 49, who practised in Lancashire and abroad. Applicant is married, with three children, now aged 9, 14, and 16 years, and he has become totally blind. Wife and children are cared for by relatives. The applicant is now studying massage in London, and hopes shortly to be qualified and earn his living. Only income £12 per year from a charity for the blind, and a little from friends. Relieved once, £10. Voted £10, and referred to the Guild.

Daughter, aged 49, of M.R.C.S.Eng. who practised at Gillingham and died in 1911, and was for some years an annuitant of the Fund. Through ill health the applicant not able to earn her living, and receives her food in return for looking after a child during the day. Has to pay rent for her room. Relieved twice, £17. Voted £12 in twelve instalments through the Guild.

Widow, aged 64, of M.B.Glasg. who practised in South Wales and died in 1913. Applicant's only income £16 per year, and her three children, all married with families, unable to help. Health very bad. Relieved three times, £24. Voted £12 in twelve instalments.

Daughter, aged 56, of M.R.C.S.Eng. who practised at Rotherhithe and died in 1879. Applicant is suffering from chronic glaucoma, which prevents her from working as a nurse. Only income from investments and friends £24 per year. Relieved seven times, £67. Voted £12 in twelve instalments.

Widow, aged 59, of L.R.C.S.Edin. who practised on the West Coast of Africa and died in 1907. Applicant has two sons who are abroad and unable to help, and one daughter, aged 36, who is an invalid, lives with her mother. Applicant has recently broken her ankle, and is incapacitated from doing any work. Only income a little occasional help from friends. Relieved four times, £48. Voted £12 in twelve instalments.

(To be continued.)

British Medical Journal.

SATURDAY, JANUARY 22ND, 1916.

TWO SCORE AND FIVE TO THREE SCORE AND TEN.

THE duty of medical men of military age and capacity—that is to say, those under 45 and physically fit—is now well defined, and the personal letter addressed by the Central Medical War Committee to all such men who have not yet applied for a commission, printed in the SUPPLEMENT for this week, and the scheme of the Scottish Medical Emergency Committee, published in the SUPPLEMENT for January 1st, explain the steps each should take. What are the duties of medical men over 45 years of age at this crisis in their country's need?

This question has hardly been mooted as yet; but the time appears to have arrived when some attention should be directed to the subject. From time to time it has been pointed out that war is a "young man's game," and catastrophes have occurred showing the unwisdom of the elderly Territorial officer whose *esprit de corps* and sense of patriotism have led him to volunteer for service abroad with his unit rather than to make way for a younger man. The duty of the medical man over 45 years of age lies in this country. If he is between the ages of 45 and 55 and physically fit, if he can be easily spared from the work in which he is engaged, and wishes to take uniformed service, it is open to him to apply for a commission in the R.A.M.C. for home service only. Though for the moment there is not much evidence that large numbers of such men for home service are required, yet it seems quite clear that the development of home service by those above military age forms one of the methods by which the strain on the civilian community and the difficulties of younger men, who may lose everything by joining the army, may be met. There must be a large number of men between 45 and 55 whose worldly position makes the sacrifice of some portion of their practice comparatively easy, whose work could be managed by their less fortunate brethren, and whose temporary withdrawal would not unduly affect the medical attendance on the community in which they live. When organization is sufficiently advanced, there should be an opportunity for employing these men as commissioned officers at home, thereby setting free younger commissioned men for service at the front, and possibly relieving from military duty some younger men who cannot well be spared. There can be little doubt that shortly a register of men between 45 and 55 must be made, and they must be enrolled. But they must remember that they will be required to engage for whole-time service, and be willing to be sent to any part of this country where their services are required.

The position of those medical officers of Territorial general hospitals described in the *Army List* as "available for service on mobilization," but often spoken of as *à la suite*, is exceptional. These hospitals were organized before the war as parts of a general scheme of the medical service of the Territorial Force, and the members of the staffs were commissioned under conditions which do not preclude

them from continuing their private practice or from attendance at the local civil hospitals, of the staffs of which they may also be members. The large increases which have been made in the number of beds in the Territorial general hospitals have in many instances rendered it necessary to take up buildings at such distances that certain members, in some instances we believe the majority, are in fact, if not in theory, altogether withdrawn from private and civil hospital practice. Further, part-time work is obtainable in many areas by men who are employed as "civil medical practitioners" without a commission; the opening for this class of work is limited at present, but it is not unlikely that further developments will become necessary.

With regard to those for whose services in any military capacity there is, by reason of age, no demand, there are two directions in which the path of duty needs mapping out: First, there is the need of making every effort to set free younger men for service; and, secondly, of taking care that those who join the army suffer as little loss as possible in consequence of their patriotism. In both these matters there is much that should be impressed upon the medical profession. Quite a number of the older men feel resentment because they are not employed in some military or semi-military capacity. They appear to think that they are being prevented from doing their duty to their country. Yet if they would only bear in mind that the military need is for younger men, and that the setting free of a younger man for service is of far greater value than paying visits to convalescent soldiers, they would find work of the highest importance. They should enter their names with the local Medical War Committee as willing to carry on the practices of absentees; wherever possible they should register themselves with the Central Medical War Committee as willing to act as locumtenents for as long a time as they can be spared from their own work; they should assist in the formation of central clinics, bureaux, or dispensaries in any area where the local committee adopts these methods for meeting the shortage of doctors; they should agree to canvass younger men and to show them how their interests can be safeguarded, wherever there seems to be any reluctance on the part of the younger men to enrol. And in the matter of safeguarding the interests of those on service there is much that needs recognition. It is not enough to agree to attend a particular man's patients for some reduced fee. It should be acknowledged that the patients of every man who has left his practice to join the army are no longer available for increasing the connexion of the man who remains at home. In every case in which a new patient presents himself for treatment it is the duty of the practitioner consulted to inquire who was the former attendant. If the patient was under the care of a man who is now serving, and if the patient for some reason declines to go to that doctor's substitute, then the practitioner newly consulted should make it clear that he only attends in the capacity of substitute; that the attendance is for the duration of the war only; and, if possible, that all accounts will be rendered by the representative of the absentee. Such a plan is perfectly workable, except, perhaps, in the case of practices among the very poorest class, in which individuals seem to change their doctor so frequently that it is impossible to decide whose patients they really are. Unfortunately, it happens that the lay community is by no means alive to its responsibilities in the matter. It is for those who remain behind in medical practice to see

that a proper view is instilled into the minds of the public, and not to permit, under any conditions, injury of the interests of those who are risking their lives as well as their fortunes.

Some of the suggestions we are now making have already been put forward in these columns. There is evidence that they have not yet fully borne fruit; and hitherto the Central Medical War Committee has been so greatly occupied in more urgent work that it has not, perhaps, been able to emphasize its opinions on matters affecting primarily the profession itself. Medical men have responded nobly to the call, but a further response is required. The call to serve with the army has now to be made on those whose difficulties in responding are possibly greater than in the case of some of the earlier recruits. It is for those whose age unfits them for active service to recognize in what directions they may best take a hand in providing the services with the medical officers required.

SERUM TREATMENT OF BACILLARY DYSENTERY.

As long ago as 1907 Kruse and Shiga independently proposed the use of serums made from the bacilli known by their names for the treatment of dysentery, and good results were said to have been obtained. In later years, however, so many other species of bacilli have been found to produce symptoms of bacillary dysentery that it has become necessary, in the absence of definite bacteriological research, to use serums called polyvalent made from several varieties of such germs. In 1910 Ruffer and Willmore prepared such a polyvalent serum, the constituents being the following bacilli: (1) Shiga-Kruse No. 1; (2) El Tor No. 1; (3) pseudo D. (Kruse); (4) Flexner, including pseudo A. (Kruse); and (5) some as yet unidentified strains. At the same time a monovalent serum against the *Bacillus dysenteriae* El Tor No. 1 was made also. In using these serums for treatment the general practice of the authors was to give an initial dose of 40 to 60 c.cm. in mild cases, of 80 c.cm. in severe cases, and of 100 to 120 c.cm. in desperate cases. These doses were repeated as required, as much as 320 c.cm. being given in twenty-four hours. The injections appeared to have a beneficial effect, manifested in from four to twelve hours after the first injection. In all cases the most striking phenomenon was the improvement in the patient's general condition; the pulse became fuller and slower, the heart sounds of better quality, the temperature fell to within normal limits, and abdominal pain disappeared. A remarkable effect upon the patient's mental condition was observed also. These striking changes in the general condition were not usually accompanied by a corresponding improvement in the character of the stools, which often became more abundant and fetid and contained more sloughs; the number passed, however, was usually diminished.

In 1913 Willmore and Savage gave a short account of the treatment of 227 cases in which the presence of bacillary infection was demonstrated. In this series it was often noted that the patient exhibited marked improvement for a few hours following the injections, only to relapse again when presumably the effect had worn off. In such cases the injections had to be repeated until the improvement became permanent. Between November, 1912, and January, 1913, the number of pilgrims that passed through the quarantine station at El Tor was 16,551. Of these 75 were admitted into hospital with dysentery

and 9 died. Out of 26 cases in which bacillary dysentery was present, 22 were treated with serums, with 2 deaths, a mortality of 9 per cent. The percentage of deaths among pilgrims in Egypt attacked by dysentery has been reduced since the introduction of serums from 53, and even from 70, to 12.

Similar satisfactory results have apparently been obtained in Japan and Fiji, as well as in France, Russia, and Germany. The notes on the treatment of diarrhoea and dysentery issued by the Advisory Committee for the Prevention of Epidemic Diseases in the Mediterranean Force¹ say of the serum available for the force that there is no doubt that in many cases it is of great value, and that the earlier it is given the better; a dose of 20 c.cm. administered by subcutaneous injection is, as a rule, sufficient, but, if deemed necessary, as much as 60 c.cm. may be given at the outset, or the smaller initial dose may be repeated. Shiga is responsible for the statement that since the introduction of anti-dysenteric serum the case-mortality from bacillary dysentery has fallen from 35 per cent. to 9 per cent. Many serums are now to be obtained, including those of Kruse, of Shiga, of the Lister Institute (Todd), and of the Pasteur Institute (Vaillart and Dopter). Shiga's rules for the administration of his polyvalent serum are: In mild cases to inject one dose of 10 c.cm.; in cases of medium severity to inject two doses of 10 c.cm. at intervals of six hours; in severe cases to inject 10 c.cm. twice a day, at intervals of six hours, for two or three consecutive days. Castellani and Chalmers state that a polyvalent serum, such as that of Shiga, is to be preferred for the treatment of cases in which a complete etiological diagnosis of the malady cannot be made. The serum, in their experience, should be given in large doses—that from the Pasteur and Lister Institutes in 20 c.cm. doses twice daily, and in very severe cases four times daily. The injection can be made intravenously or under the skin of the abdomen or flank, using ordinary aseptic precautions. Such injections, they believe, as a rule need not be continued after the second or third day. In some instances the injections cause a slight rise of temperature or even urticarial-like eruptions and pains in the joints. According to their experience the serum has a marked effect upon the disease, hastening the cure, ameliorating the symptoms, and reducing the mortality.

Other observers have not perhaps met with such good results, and it is a fact that there are cases in which the serum appears to fail. The cause of these failures may quite well be that the individual case of the disease is due to some species or strain of bacillus not contained in the serum that has been used. This is a possibility which must not be lost sight of.

Again, it is quite possible that in the past amoebic cases may have been so treated, as well as cases of diarrhoea and bowel troubles not necessarily connected with dysentery, and the Mediterranean "notes" from which we have already quoted say that "in cases of doubtful etiology there should be no hesitation in employing a combined therapy of emetine and polyvalent serum." The diagnosis of the various forms of dysentery is not easy, and until this has been put on a more scientific basis much confusion must necessarily exist as to the treatment most suitable for each individual type. On the whole, however, the bulk of the evidence is in favour of the use of serums in bacillary dysentery. It is important that records should be carefully kept of all cases so treated, as the statistics so obtained will be of the greatest use in the future.

¹ Journ. B.A.M.C., November, vol. xxv, p. 478.

THE SOLDIER'S HEART.

THE war has emphasized the importance both of an appreciation of the physiological variations in the action of the normal heart and of a knowledge of the means by which temporary or slight cardiac disturbances may be distinguished from those of greater moment. The subject is one on which opinions vary widely, and in which finality has not yet been attained. Knowledge of cardio-pathology has increased so rapidly during the last few years, and so largely by the employment of technique which is beyond the reach of most, that it is not surprising that by some medical examiners recruits have been rejected or soldiers invalidated for reasons which subsequent examiners have considered inadequate.

To meet these difficulties as far as may be, a memorandum was drawn up by Sir James Mackenzie and circulated by the War Office to those whose duty it is to examine recruits. This memorandum, which was published in our issue of October 16th, 1915, enjoins the need for gauging the functional efficiency of the heart by ascertaining how it responds to effort. Physiological murmurs, it states, are always systolic in time, and it advises that murmurs should be held to be negligible if the candidate's response to effort is normal and his heart is not increased in size. After assuming that irregularities indicating serious disorder would be associated with such diminution of the functional efficiency that their possessors would not seek to recruit, it deals more particularly with two other forms of arrhythmia—"the youthful type" and that accompanied by extra-systoles. The former, which varies with respiration, is regarded as of no importance since it occurs with perfectly healthy hearts. The latter should lead to the candidate's rejection only if the heart's efficiency is impaired and its size abnormal. It is also pointed out that during examination those who are perfectly healthy may suffer from palpitation or excited action of the heart, the beat becoming forcible and rapid; sometimes a systolic murmur may be heard. If such a candidate be told to lie down and breathe slowly and deeply for a few minutes the cardiac action becomes less violent and the rate slows during expiration. Contributions from subsequent writers showed that the data laid down in this memorandum were not entirely acceptable to all.

A study of "soldier's heart," or "the irritable heart of soldiers," approaches the subject from another standpoint, and was the basis of a discussion held at a meeting of the Section of Pharmacology and Therapeutics of the Royal Society of Medicine on January 18th, to which Sir James Mackenzie and his collaborator, Dr. R. McN. Wilson, contributed the opening papers. The disorder attracted much attention during the American Civil War, and was exactly described by Henry Harthorne in a paper published in the *American Journal of Medical Sciences* in 1864. In the same year the British Government appointed a committee to inquire into the heart conditions prevailing in the army. It sat for five years, and came to the conclusion that the form of accoutrement then in vogue, by restricting the heart's action, caused its "irritability." One of its recommendations was that the principle of the brace should be adopted, and this was afterwards acted upon, but the irritable heart remained. Another theory, initiated by Surgeon Arthur Davy in 1876, has proved equally fallacious. In his opinion "setting up" drill was the cause. It acted, he said, by over-expanding the chest and thus dilating the heart. But, as Dr. Wilson points out, cases are now met with among soldiers who have had

little or no drill in circumstances where this cause could be excluded.

The observations of Sir James Mackenzie and Dr. Wilson suggest that the malady should be regarded in an altogether different light. They have examined about 400 soldiers who have been certified and treated as having heart affections. In their opinion, in at least 90 per cent. of these the heart is not primarily at fault, and the treatment suitable for them is widely different from that appropriate for patients suffering from heart failure. They consider the condition one of general exhaustion, and the circulatory symptoms but evidences of a general state. In the majority of the cases the onset of the exhaustion was found to be connected with an infection; in a few, a history of a very strenuous life preceding the symptoms was alone obtainable. These observers make a clear distinction between the symptoms arising from infection of the heart and from cardiac failure on the one hand, and those of the "poisoned" heart, as they term the "irritable heart" of soldiers, on the other. The principles of the treatment which they recommend are a natural corollary of this conception of its etiology: they are directed to increasing the general health of the body in such a way as to increase the natural resistance to infection, to eliminating toxic influences, and to bracing up the patient bodily and mentally. They therefore advise fresh air in plenty and judicious exercise in the fresh air, and disapprove of the way in which such patients are often kept in bed for long periods under depressing circumstances. That exercise should be selected which gives the man most pleasure, and should be indulged in so long as it causes neither distress nor discomfort. It is clearly of great importance that this view of the nature of "soldier's heart"—a view with which the sense of the meeting was in general agreement, though several speakers attached importance to the existence of hyperthyroidism in a certain proportion of cases—should be known to medical officers in order that the soldier may be safeguarded from the depressing effect which a diagnosis of "heart disease" engenders.

WAR PENSIONS.

The first meeting of the Statutory Committee of the Royal Patriotic Fund Corporation constituted by the Naval and Military War Pensions Act, 1915, was held at St. James's Palace on January 17th, under the presidency of the chairman, the Prince of Wales, who, in opening the proceedings, said that the Committee was empowered to deal with the pensions and allowances granted not only to those who had been engaged in this, the greatest war the world has ever seen, but also to their wives, their families, their widows, and dependants. The Committee would be able to deal sympathetically with the cases of widows and dependants who might need more individual treatment than could be given under the necessarily somewhat rigid system of Government departments. The Committee was not only authorized to supplement in exceptional cases the scale of State pensions, but also to take into consideration the position of dependant persons not hitherto recognized by the State. Another class to whom the sympathy of the whole nation went out, and who might count upon the hearty consideration of the Committee, were those who in the prime of manhood and vigour of health had been permanently disabled. They would receive substantial pensions from the State, but the duty of the Committee would be to initiate schemes of training and means of finding employment for them, so that they might be enabled to feel that they were still active members of the community. The Committee contains representatives of

many of the voluntary associations which have already done so much to ensure the sympathetic treatment of the families of men with the colours and of the widows and orphans, and the Prince expressed the hope that they would cordially co-operate with the Committee. Much quiet unselfish work had, he said, been done since the beginning of the war by thousands of men and women to make certain that, as far as possible, men fighting our battles should be free from anxiety as to the well-being of their families at home, but it would be the duty of the Committee to see that this good work was adjusted and developed. The Prince concluded by intimating that it would not be possible for him during the continuance of the war to carry out fully his duties as chairman, and in fact he returned to the British army in France on the following day, but he expressed his confidence that the vice-chairman, Mr. Cyril Jackson, could count upon the loyal and implicit confidence of all the members. Afterwards the Committee appointed three subcommittees: organization and general purposes (8 members); finance (6 members); pensions, grants, and allowances (12 members). The chairman, vice-chairman, and Mr. Hayes Fisher, Parliamentary Secretary to the Local Government Board, will be *ex officio* members of all committees. Mr. Hayes Fisher informed the Finance Committee that the Chancellor of the Exchequer would recommend Parliament to place a State grant of £1,000,000 sterling at the disposal of the Statutory Committee. Until a secretary is appointed, Lieutenant-Colonel Alfred Welby, Secretary of the Royal Patriotic Fund Corporation, will act, and in the meanwhile the work will be carried on at the offices of the Corporation, 17, Waterloo Place, S.W., where all letters should for the present be addressed.

GRANTS TO UNIVERSITIES AND UNIVERSITY COLLEGES.

THE Board of Education has issued in two bulky volumes its report for the year 1913-14 on those universities and university colleges in Great Britain which are in receipt of grants from the Board. The grants to English universities and colleges for the financial year 1913-14 amounted to £149,000, and those to the three colleges in Wales to £25,500. The volumes also contain reports from other universities and constituent colleges of universities in receipt of aid. Among these are included for the first time reports from the Medical Department of the University of Cambridge and the Medical School of St. Bartholomew's Hospital (University of London). Owing to the war the issue of these volumes was delayed by the pressure of work caused by the absence of many members of the Board's staff either serving with the military and naval forces or temporarily transferred to other departments, and the Board does not intend to publish volumes of reports for the year 1914-15. From the beginning of this year the influence of the war became more and more disturbing, and it was soon clear that the teaching centres would suffer severely from the decrease in the number of students. In the autumn of 1914 preliminary inquiries were made to ascertain the extent of the financial loss which might be anticipated, and as a result the payment of a special grant to university institutions was recommended. The Treasury, recognizing the justice of these claims, made provision accordingly in the estimates for 1915-16. It is hoped that in this way something may be done to prevent any permanent decrease of efficiency of university education. But it cannot be denied that the war has inflicted irreparable losses on education, and that the year 1913-14 will for a long time to come represent the high-water mark of educational achievement in this country. The report is therefore of more than usual interest, as it relates to the last academic year before the outbreak of the war. During the past year the vital dependence of industry upon the higher branches of scientific research

has been very clearly shown, and it is recognized that university institutions will play a great part in providing the scientific needs of industry on a scale calculated to put this country on equal terms with the best-equipped rival. The Board has recently put forward a scheme for the organization and development of scientific and industrial research. Under this scheme a Committee of the Privy Council, responsible for the expenditure of the funds provided by Parliament for the purpose, has been established, and also an Advisory Council responsible to the Committee of Council and composed mainly of scientific men with knowledge of industries dependent on research. Sir William McCormick is Administrative Chairman of the Advisory Council and also of the Board's Advisory Committee on University Grants, so that it is hoped to ensure harmony of action between the Research Council and the Universities Committee. Attached to the report are numerous tables showing the income, expenditure, and number of students of the various teaching centres, which are divided into two main groups, according as they are in receipt of "Exchequer" grant, or of grants not falling under this heading. To this latter category the Cambridge and St. Bartholomew's medical schools now belong. In England the income of institutions in receipt of "Exchequer" grant showed an increase in this last year before the war of over £6,000 from fees, an increase of more than £5,000 from endowments, and an increase of nearly £5,000 from grants by local authorities. The expenditure of institutions in receipt of "Exchequer" grant in England showed a rise of about £18,000. The total expenditure of the medical schools in London, excluding St. Bartholomew's, showed an increase of £3,000 over the previous year. The cost of maintenance of premises fell by £1,000, while the expenditure on teaching, salaries, and laboratory maintenance rose by £4,000. In England the total number of full-time students in institutions receiving "Exchequer" grant numbered 7,756, as compared with 7,666 for the year 1912-13, the increase being equivalent to 1.2 per cent. of the total. It was due to a marked rise in the number of university students, for there was a fall in the number of training college students. The total number of part-time students showed an increase of about 300. The number of full-time students at institutions not in receipt of "Exchequer" grant (and for this calculation the statistics for Cambridge and St. Bartholomew's were not available) had risen from 1,810 to 1,921. The medical schools in London showed an increase of 95, the London School of Medicine for Women leading with an increase of 34 students. It is interesting to find that while the number of students of arts and pure science in England had continued to fall, the number of students in medicine, engineering, technology, and agriculture had risen, the rise being greatest in medicine. In two years the total number of medical students had increased by 283, or nearly 11 per cent. In 1912-13 this increase was practically confined to the medical schools in London. In England the percentage of students admitted under 17 had decreased from 4.9 to 3.2; in Wales, however, it had risen from 1.6 to 2.9.

INHALATION OF STONE DUSTS.

THE Explosions in Mines Committee has issued a report¹ by Dr. J. S. Haldane, F.R.S., on the effects of inhaling dusts applicable for stone dusting in coal mines. In previous reports experiments bearing upon the effects of inert dusts in preventing or limiting explosions in coal mines were detailed, and while it is impossible to say to what extent the use of incombustible dust will render explosions impossible, there is a belief that the number of explosions will thereby be diminished and their violence limited. Questions, however, have arisen as to whether the distribution of such fine dust as silica may not be

¹ Cd. 8122. Price 2d.

injurious to the lungs of the miners. Professor Beattie, of Liverpool, has found that the dust of argillaceous shale is innocuous. Since the publication of his report Mr. A. Mavrogordato has carried out fresh experiments which confirm the opinion. If there is danger at all it is more likely to come from flue dust, and this should certainly be interdicted. The amount of pulmonary phthisis among the tin miners of Cornwall is still far too high. Their death-rate compares most unfavourably with that of coal miners. It is inadvisable, therefore, to introduce into a coal mine any form of dust which, while possibly preventing explosions, might yet become a cause of pulmonary disease. The dust of uncombined crystalline quartz has been found to be dangerous. In fact, it is to the presence of quartz in the gold mines of South Africa that the large amount of silicosis in the Transvaal is attributed. The granite cutting industry also is an unhealthy occupation, owing to the fact that granite contains quartz and the silicates mica and felspar. In steel grinding it is difficult to say how much of the lung disease is due to the steel and how much to the grindstone. Animal experiments have shown that intense exposure to dust produces fibrosis of the lungs, and later on there is always the possibility of tubercle becoming engrafted upon the affected lung. The opinion is expressed that shale dust when inhaled is no more deleterious than coal dust, but that under all circumstances it is well to reduce to a minimum the inhalation of dust of all kinds.

HOSPITAL CONSULTATIONS AND THE PRIVATE PRACTITIONER.

THE Massachusetts General Hospital is about to open a consultation clinic for the benefit of people of limited means. On two days in the week, the *Boston Medical and Surgical Journal* states, patients referred by their own doctors will be received in the out-patient department for "consultation and diagnosis only." Doctors are requested, if possible, to accompany their patients. When a practitioner is unable to do this he will be expected to send a letter referring the patient to the hospital. The doctor will in due course be informed as to the diagnosis made, and treatment will be suggested. An admission fee of £1 will be charged. When an x-ray examination is needed an additional fee of 8s. to 12s. will be charged. For certain other laboratory tests charges not exceeding 4s. will be made. This covers any further visits which may be necessary for a diagnosis. The result of this experiment will doubtless be closely, and even jealously, watched. Our Boston contemporary, while admitting that "judged by a conservative standard it is an encroachment by the hospital upon the territory of individual physicians," says that "from a more enlightened point of view it is a further step towards improving the service which the medical profession as a whole renders the public." The beneficial effect "will not be due to successful individual diagnoses alone. It will follow, later on, that people will demand more accurate diagnoses, and the application in their own cases of some of the more scientific diagnostic methods such as they or their friends have seen employed at the hospital." The Boston journal thinks it improbable that the clinic will injure the general practitioner. "He will be aided in his management of the case; and, if the disease is one which he is unsuited to treat, the sooner he learns that fact the better for his reputation." This seems to us a somewhat Olympian way of regarding an innovation which may have very far-reaching social and professional consequences. There are, of course, certain obvious advantages to the practitioner in the scheme if it is worked by the hospital staff in a spirit of professional loyalty. If he goes to the clinic with his patients these visits will help to keep him abreast of the progress of knowledge. But great care will be necessary if friction is to be avoided, and the scheme is doomed to failure unless his cordial co-operation is secured.

INDUSTRIAL LIGHTING.

THE lighting of factories and offices—which will in due course be the subject of legislation based on the recently published report of the Home Office Committee—is at present in a transition stage. Until quite recently local illumination held the field, but there is now an increasing tendency to abandon the lamp over the individual machine or desk, and to substitute powerful light sources with suitable reflectors placed high up near the ceiling. This plan has the advantage of avoiding inconvenient shadows, although local lighting is still essential in a comparatively small number of cases where the work is of a specially delicate or complicated character, or where, in the manipulation of fabrics, a great deal depends upon the play of light and shade. In clothing factories local lighting is already being widely replaced by general illumination, and in one of the very latest factories, now working on khaki material, general lighting with half-watt lamps has been adopted. One circumstance which has helped to bring general lighting into favour in factories is the simplification of machinery and the diminution of shafting and belts owing to local electric driving. Overhead shafting renders general lighting impracticable, owing to the interruption and flickering caused thereby. One point which was brought out in the course of the discussion on this subject at a recent meeting of the Illuminating Engineering Society was the supposed physiological preference for local as against general lighting. The Chairman, Mr. F. W. Goodenough, said that in cases in which the work demanded concentration of attention for long periods the workers found it restful to glance up from their brightly illuminated surfaces to the subdued surroundings. The lighting in the sorters' department of the General Post Office has been modified in response to a demand of this kind on the part of the men. The physiological basis of this problem, however, is still obscure, and requires further study. Another point of importance which was insisted upon by the opener of the discussion, Mr. J. S. Dow, was the value of reflected light from the surroundings. This reflected light is most useful in strengthening the illumination in parts of the room furthest from the lamps and keeping it above the minimum necessary for safety. In addition to this, it is now recognized that most objects cannot be completely seen unless they are illuminated from many different directions, and in some American factories the floor and non-moving parts of the machinery, as well as the ceiling and walls, are painted in a light colour.

THE MEDICAL EXAMINATION OF RECRUITS.

ATTENTION has been called to an article which appeared in the *Sunday Chronicle* for January 9th, headed "£80 a Week," stating that a number of correspondents had written to the editor enclosing cuttings from newspapers which state that in the last big rush of recruiting many doctors charged 2s. 6d. for each recruit examined, and that in some cases individual doctors were charging as much as £80 a week. After some gratuitous remarks about the attitude of doctors towards the Insurance Act, the editor adds, "It seems that the Government had a short way with these gentry, and cut down their charges to a maximum of two guineas per day." Some of the correspondents are said to have waxed sarcastic at this exhibition of "patriotism," and asked if these particular medical men have any right to criticize Welsh miners or Clyde engineers, and the editor of the *Sunday Chronicle* says in reply, "We do not think they have the right, but are quite certain that they will be very prominent in exercising it." In the issue of the *Sunday Chronicle* for January 16th a letter appears signed by Dr. Joseph Jones of Leigh, Lancashire, pointing out that it is all nonsense to talk about doctors charging £80 a week,

as they knew quite well beforehand what the rate of payment was and the maximum for any day. As was stated in these columns last September, the rate paid before the war was 2s. 6d. a man, but when recruiting on a large scale began in September, 1914, it was arranged that the total paid should not exceed 24s. for any one day. Since March 12th, 1915, the rate paid in most, if not all, commands is on a sliding scale. For one to four men it is 2s. each; for five to nine it is 10s.; for ten to nineteen 20s.; for twenty to twenty-nine 30s.; and for thirty men or more 40s., which is the maximum. The sum allowed to county associations for the medical examination of recruits of the Territorial Force is 1s. a head. Dr. Jones in his letter points out that doctors have at times during the rush of recruiting been in attendance at the recruiting offices from the opening in the morning until 11.30 p.m., not because they expected to be paid, but because they knew the country wanted the work to be done, while at other times doctors have hung about the recruiting offices all day and only had perhaps one or even not one recruit to examine. In a note to this letter the editor says: "It is a fact that some doctors sent in accounts for £50, £60, or £80, for examining recruits during the last week of the Derby scheme. Our correspondents only referred to these particular cases and made no imputation at all upon the patriotism of the general body of medical men. If they had done we should not have published their letters." It would, perhaps, have been better to have ascertained the facts with regard to the authorized scale of payment. The medical examination of recruits is thankless work, and though it may be well to correct evident mistakes, the doctor-baiters are perhaps best left severely alone to pursue their hobby.

Medical Notes in Parliament.

The Central Medical War Committee.

MR. TENNANT has made written answers to three questions by Mr. Shirley Benn (January 12th). The first question was why the medical profession is not starved, since a doctor represented a skilled worker who was not easily replaced and whose training occasioned considerable outlay and occupied a long period of time. Mr. Tennant's reply was: Special arrangements have been made with regard to the recruitment of the medical profession with a view to ensuring all adequate attendance on the troops without unnecessarily dislocating the medical needs of the civil population. The question of starring does not arise.

The second question was, under whose authority the Central Medical War Committee, now occupied in recruiting doctors to the Royal Army Medical Corps, was chosen; by whom were its powers defined; what were those powers; and by whose nomination had its members been selected.

Mr. Tennant replied as follows: The Committee referred to in the question was, I am informed, appointed, and its terms of reference settled, by the British Medical Association at its Annual Representative Meeting in July last; it was not confined to members of that Association, and the Committee co-opted five additional members representative of universities and colleges and of other medical bodies. One of the members of the Committee, being a member of the War Office Medical Advisory Board, was named by the Director-General to represent the Army Medical Service on the Committee. The terms of reference are as follows:

To organize the medical profession in England, Wales, and Ireland in such a way as will enable the Government to use every medical practitioner fit to serve the country in such a manner as to turn his qualifications to the best possible use; to deal with all matters affecting the medical profession arising in connexion with the war; and to report to the Council (of the British Medical Association).

After a conference at the War Office with the Director-General of the Army Medical Service, the Committee was informed on August 9th, 1915 (in a letter which has been published) that the Director-General hoped to receive from the Committee much help in his work of providing officers

for the Royal Army Medical Corps, and was glad to recognize the Committee as a medium for dealing with the great problem which faced the medical profession—namely, how to supply medical officers for the forces and at the same time to protect the needs of the civil population; and the Committee was accordingly authorized to make appeals to the profession with the object of securing these needs.

A further conference took place at the War Office with the Director-General of Recruiting on November 5th last on the same subject, and to the same effect. As a result of these conferences, this Committee, which has local committees in all parts of the country, has been endeavouring to procure and to co-ordinate offers from members of the medical profession of service in the Royal Army Medical Corps. Applications for such commissions are decided upon by the War Office after they have been referred to this Committee for consideration in relation to the medical needs of the civil population in the area concerned in each case, and after consultation with the Insurance Commission and, where necessary, with the Local Government Board and the Board of Education. Analogous arrangements exist in regard to Scotland. I should add that the War Office have received, and are receiving, very valuable assistance from these committees.

Mr. Benn's third question was whether the Government had sanctioned the recruiting, through the agency of the Central Medical War Committee, of medical men up to the age of 45, the limit of age for the rest of the nation being 41. Mr. Tennant answered as follows: The age limit referred to in the question relates to medical men applying for commissions in the Royal Army Medical Corps, and not to recruits for the combatant services in which the age limit of 41 applies.

War.

Medical Students.—Mr. Tennant, in a written reply to Mr. Shirley Benn (January 12th), who asked as to the risk of cutting off at its source the supply of medical aid both for the army and for the civil population incurred by recruiting first and second year medical students, has stated that the present policy was undertaken after most careful consideration. He added that the statistics bearing upon the matter were being further examined.

Recruits Physically Unfit.—Several questions have been asked with regard to the disposal of recruits found physically unfit. Mr. Tennant stated on January 12th that men already rejected for military service or discharged from the army on account of wounds or ill health who presented themselves for attestation would be included in the number of medically rejected. Such men, if they had not thought it necessary to attest, would not be called upon to serve in any event if their physical disability still rendered them unfit for any form of military service. On January 13th Mr. Tennant said that he hoped shortly to be able to state what arrangements it was proposed to make to give some distinctive badge to men discharged from the army as medically unfit.

Hammer Toes.—On January 13th Colonel White asked whether a considerable number of young soldiers were pronounced unfitted for drafts or were discharged from the service owing to their suffering from hammer toes or similar disability, and whether he would consider the advisability, in the less aggravated cases, of having these men fitted with surgical boots which might render them fit for service, in any event with a non-combatant unit. Mr. Tennant said that in the opinion of his medical advisers the issue of surgical boots to the men mentioned was not likely to render them fit for service; even if such boots were issued it would be quite impossible to replace them if they were lost or worn out on service.

Discharges for Physical Incapacity.—In reply to questions addressed to him by Mr. Hogge (East Edinburgh), Mr. Currie (Leith Burghs), and others, in regard to men discharged from the army with disease alleged to have been contracted before enlistment, Mr. Tennant has stated that each case is judged on its merits, the fullest consideration being given to each by the Commissioners of Chelsea Hospital and the army medical authorities. The suggestion that all disease subsequently manifesting itself in a man who had passed the doctor as a recruit should be regarded as due to military service could not be accepted. It was not possible for the military department to take responsibility in the case of men who had not contracted

illness in the service of the State, even if they had passed the medical examination when recruited. It was possible that the disease might not then have been detected; there might have been previous illness. Asked by Mr. Currie with regard to the case of men who had some latent disease which emerged owing to the hardships of military service, Mr. Tennant said that, speaking generally, it would be for the military authorities to state whether they considered that the actual service of the State had been the reason for the breakdown; if it had been, the man would receive the pension to which he was entitled. On January 17th Mr. MacCallum Scott asked whether officers holding temporary commissions invalidated out by a medical board after serving during the present war would be liable to enrolment under the Military Service (No. 2) Bill, and whether single men honourably discharged on medical grounds from the army during the present war would be liable to enrolment under the bill. In reply Mr. Tennant said that individuals invalidated out of the service, whether officers or men, would, *prima facie*, be eligible for exemption under the bill.

Australian Medical Corps.—Captain Amery asked the Under-Secretary of State for War whether Lieutenant-Colonel J. W. Barrett, Australian Medical Corps, occupied the Imperial appointment of Assistant Director of Medical Services on the staff of the Director of Medical Services, Egypt, and consulting oculist to His Majesty's forces in Egypt; whether he was removed from these offices without inquiry by the Australian Government on a recommendation of the Army Council, which the General Officer Commanding in Egypt subsequently pointed out was due to a misunderstanding; whether a court of inquiry had been held, and what was the finding of that court; and whether, if that report is favourable, the Army Council is prepared to reinstate Lieutenant-Colonel Barrett, or whether he is prepared to make any statement with regard to the value of the work done by Lieutenant-Colonel Barrett. Mr. Tennant: I believe the facts as stated in the first two parts of the question are substantially correct. A court of inquiry was held in Egypt in October last year, and in its finding the court exonerated Lieutenant-Colonel Barrett, and spoke in the highest terms of his work. The High Commissioner of the Commonwealth was informed that there was no objection to Lieutenant-Colonel Barrett being employed in Egypt or elsewhere, provided the Government of the Commonwealth concurred.

Recruits' Eyesight.—Mr. Tennant has returned written answers to a series of questions by Sir John Rolleston as to the examination of recruits for defective vision. Mr. Tennant said that special ophthalmic surgeons were available in all commands, to whom would be referred all cases of doubt or difficulty, and cases in which it was thought that the defective vision could be corrected by glasses. The certificates of medical eye specialists were treated in the same way as certificates from any other medical men. They might aid the medical examiner of recruits, but could not absolve him from his responsibility in passing or rejecting the recruit.

Vaccination.—In reply to Mr. P. White, the Parliamentary Secretary to the Local Government Board, on January 13th, stated as follows: The number of successful vaccinations for which vaccination officers receive certificates at all ages in England and Wales was, in 1913, 430,470, and in 1914, 404,616, and the number of declarations of conscientious objection to vaccinations in 1913, 308,235, and in 1914, 321,313. I cannot give the actual number of children vaccinated, nor the figures for 1915, which are not yet available. It appears from the criminal statistics for the year 1913 that 146 persons were proceeded against in that year for offences against the Vaccination Acts. The statistics for 1914 and 1915 have not yet been published.

Madras Medical Council.—In reply to a question by Sir J. D. Rees as to the feeling alleged to be aroused among Ayurvedic physicians and hakims in the Madras Presidency by the action of the Madras Medical Council under the Madras Medical Regulations Act, 1914, in respect of Dr. Krishnaswamy Iyer's alleged covering of an Ayurvedic physician, and whether it was proposed to amend the Madras Act so as to bring it into line with the Bombay Medical Act, 1912, Mr. Chamberlain said that he had no official information on the subject.

THE WAR.

GENERAL AND STATIONARY HOSPITALS.

(From a Correspondent in Northern France.)

The differences between casualty clearing stations and other hospitals are well marked; those between general and stationary hospitals may more easily be overlooked. In certain instances in France they are almost undiscernible. They do, however, differ as a rule very considerably in point of size, and in any case the theoretical or official distinction between them should not be forgotten by students of army medical administration.

Speaking metaphorically, it may be said that general and stationary hospitals are brothers, and the casualty clearing stations their distant cousins. Of the two brothers the elder is a portly citizen who lacks nothing that wealth can provide, and lives as a rule in the very best part, that is to say, at some military base. His guests, like himself, are supposed to be always persons of importance—in other words serious cases—and he is invariably prepared to receive at least 520 of them; also, whatever their number, he is able to provide them with all sorts of luxury in the way of up-to-date treatments. Finally, he is in a position to re-equip them completely in the matter of clothing; and, on the termination of their visit—if this has been a success—he can hand them over to one of his satellites, a convalescent camp. He is, in short, almost the military equivalent of a leading hospital in a medical centre at home.

The younger brother—the stationary hospital—often receives the same kind of guests, but is much less imposing in appearance. Even though he chance to be the immediate neighbour of his relative and to be really quite as well-to-do, he maintains an establishment which is much less elaborate in point of equipment and also smaller (200 beds). Likewise he is supposed to be a person of more democratic tastes and hardier constitution. Consequently he usually lives in a poorer part than his brother. His natural habitat, in fact, is some spot on the lines of communication, where he can afford temporary accommodation for important persons or receive guests of a humbler sort, that is, men likely to recover from their wounds or sickness with rapidity, and whom it is consequently desired not to remove further than need be from their own units. His nearest equivalent in civil life is perhaps a county infirmary.

The third of the group is quite a different kind of person. A dweller in the byways, he reckons little of appearances. Provided he has room for 200 guests and as many more as happen to arrive he is content with the mere necessities of life in the matter of food and furniture and all other items. Many of his guests are more distinguished than any of those received by his cousins, but whatever their character he always passes them on to the latter as soon as circumstances permit.

All three are war-time institutions; in other words, they do not exist when the army is on a peace footing, but are ordered by the regulations regarding the Expeditionary Force (as revised and published in 1914) to be created on mobilization in the proportion of 2 general hospitals, 2 stationary hospitals, and 1 casualty clearing station to every division in the field. As the same regulations also direct that accommodation on hospital ships (220 cots per division) and on ambulance trains (room for 100 lying down cases per division) shall be simultaneously mobilized, it will be seen that the total accommodation provided is well over 10 per cent. of army strength.

This being the case, any one who has followed the debates in Parliament, and therefore knows the approximate strength of the British forces in France, can calculate for himself the vast total accommodation which the medical authorities in France would have been justified in raising had they chosen to act strictly in accordance with the regulations. Fortunately, however, for the taxpayer, for the medical profession, and for the civil population in Great Britain, this has not been their attitude. What they have done in reality is to comply, not with the letter of the regulation, but with its spirit. They have, in short, from beginning to end kept their accommodation in medical units of all kinds down as low as the position immediately in view seemed to justify. The enormous

economy thus effected in the way of personnel and all other directions will be realized only when and if the precise figures are published. For the present this, for obvious military reasons, is not likely to be done.

The immediate outcome of this attitude towards the general problem of how to secure that there shall never be any shortage of beds or other accommodation in France, without trenching too far on home resources, has been that instead of raising new general and stationary hospitals for every division that has arrived, the desired proportion of beds has more often been secured by expanding the accommodation of existing units.

This expansion has naturally not been level throughout, so there are a good many stationary hospitals whose accommodation is not obviously less than that of a general hospital. This is one circumstance which has tended to obscure the difference between the two types of institution, but there are others, perhaps of more importance. For example—the lines of communication are, practically speaking, quite short; it has been unnecessary to string out the stationary hospitals along them; they are commonly to be found at bases in the immediate locality of the general hospitals where they are housed on identical lines.

Another circumstance is the siege-like character of the military operations during the last fourteen months. This has enabled the medical authorities to avoid moving hospitals as frequently as would otherwise have been the case, so that many stationary hospitals have occupied the same site for many months; some for over a year. Their commanding officers have thus had time to beg, borrow, or steal all sorts of extra equipment and so bring up their hospitals to the level of a general hospital, both internally and externally. The zeal in this respect of the commanding officers, both of general and stationary hospitals—that is to say in regard to striving constantly towards perfection—is beyond all praise, and the hopeful spirit they exhibit is often quite remarkable. Many, for instance, start elaborate gardens, if they have any ground, around their huts and tents, and some have done so with much success. These things they do notwithstanding their consciousness that even if their hospital is not suddenly moved on elsewhere, they themselves may be transferred to another sphere of activity and leave the harvest to be reaped by a brother officer. Nor are such endings to their efforts by any means rare. It would sometimes seem, indeed, as if Nemesis kept a special watch for commanding officers who are too successful in the directions indicated.

A third factor is the importance that the medical authorities in France attach to the utilization of scientific methods. It has led to their gradually providing almost all stationary hospitals with annexes, such as the regulations would seem to imply shall be attached, as a rule, only to general hospitals—for example, x-ray departments, and often pathological laboratories.

A further circumstance which has had the effect of helping to eliminate the difference between the general and stationary hospitals in France is that some of the latter have been told off to do special work, and have thus acquired an importance which they would otherwise not have possessed. For instance, one stationary hospital began at quite an early date to deal exclusively with cases of infectious disease, and little by little has developed into an institution with nearly 1,000 beds. A second, which receives none but officers, has converted itself into the equivalent of a first-class nursing home; while a third, which has expanded despite the great success of its work, devotes its energies to the rapid restoration of their military efficiency to men suffering from venereal disease.

These are the circumstances which have mainly contributed to render the difference between general and stationary hospitals less discernible than it was in the first months of the war, and some of them have had a corresponding effect on the casualty clearing stations as a class. It is not common for any of these to remain in the same place very long, but some of them are housed in excellent buildings, and have managed to get hold of a sufficient number of bedsteads and other fittings to secure that at any rate one or two of their wards shall not be distinguishable from those of a stationary hospital of the more elementary kind. What is still more important, they all now include in their staffs members either of Queen

Alexandra's Imperial Nursing Service or of the other nursing bodies which are now sharing its labours.

The net result is eminently satisfactory. There are few hospitals in France which could not give points to any of those which came into existence in South Africa during the last great war, and the general level in respect of the comfort of patients and of facilities for doing professional work of the best kind falls little if at all short of that of permanent civil hospitals in Great Britain.

Nevertheless, the official distinction between the three types of institution still remains, and should a general and prolonged advance take place it may be expected to become once more plainly visible. In other words, a casualty clearing station is officially only a hospital so long as it cannot pass its patients down the lines of communication; it is also expected to do this as quickly as possible, not keeping its patients longer than their condition renders imperative, or performing any operations other than those of necessity. Beyond mattress cases, it has little ward or allied equipment other than what it can carry in its own field panniers, and it is expected to keep ready to move at almost a moment's notice. Of this fact some commanding officers of casualty clearing stations remind themselves by keeping the motor lorries allotted to them within direct view and making a point of using them daily for some purpose or other.

Despite its name, mobility is also expected of a stationary hospital; for this, too, is a field unit. It possesses a good deal more equipment than a casualty clearing station, but its beds and bedding are only of barrack-room type, and it is self-dependent in the matter of medical comforts and surgery requisites. That is to say, it must carry everything it requires for any reasonable period in panniers, and it must never be surprised if asked to move on to some place at a distance from any centre at a notice of twenty-four hours or so.

The position of a general hospital, on the other hand, is considerably different. Its normal equipment is not essentially dissimilar to that of a civil hospital, and includes ordinary bedsteads, hair mattresses, bedside tables and the like, as well as plenty of surgical desiderata. It also has the advantage of knowing that if it is ever required to move it is likely to receive plenty of notice, and that in any case it will never be sent to a place at which it cannot obtain forthwith any stores or extra equipment that it may require.

All three types of hospital possess tents and marquees, but are expected to utilize permanent buildings if suitable ones be available.

TREATMENT OF ACUTE DYSENTERY.

At a meeting at Alexandria on October 17th, 1915, Surgeon-General BARTIE, V.C., Principal Director of Medical Services Mediterranean Expeditionary Force, Egypt and Malta, being in the chair, a discussion took place on the treatment of acute dysentery.

Lieutenant-Colonel Sir RONALD ROSS, who opened the discussion, after a short historical survey, drew attention to the relatively greater severity of the disease among the troops from Britain, Australia, and New Zealand compared to that among those from India. Emetine hydrochloride appeared to have proved very successful, but a certain percentage of cases remained refractory. Such were "running dysenteries," due probably to post-amoebic colitis. In older cases, especially of "running dysentery" not cured by emetine, he was still partial to ipecacuanha powder. Subsidiary treatment, oral and rectal, was by no means to be despised. Bismuth seemed to have proved distinctly useful. Oils appeared to be suitable *a priori* grounds, and olive oil had for long been used extensively in Italy. Much difference of opinion existed as to the value of rectal injections in acute dysentery; in chronic dysentery they were often essential. He could testify to the value of hot hip-baths in cases with severe tenesmus. Regarding diet, his personal feeling was against too much broth, meat extracts, and eggs, and still more against large volumes of fluid of any kind, especially in "running dysentery." In conclusion, he pleaded that the complications should not be forgotten—chronic dysentery, often with stricture and a life of misery, and hepatic abscess. Rogers had found that in the British army in India more than 14 per cent. of cases developed the latter. (The report of Sir Ronald Ross's lecture before the Royal Society of

Medicine on December 20th, 1915, will be found in the BRITISH MEDICAL JOURNAL of December 25th, p. 927.)

Major McCARRISON, I.M.S., said that dysentery had accounted for slightly over 9 per cent. of the total Indian casualties from the Mediterranean. The mortality had been *not*, and the cases had usually been mild. In a considerable number cure had rapidly resulted from rest, castor oil or salines, and appropriate diet alone. Emetine had only been necessary for a minority. The majority of the cases were amoebic in origin. He was of opinion that large doses of emetine were not indicated; half a grain twice daily for one week, and once daily for a few days longer, was sufficient and safe. If the condition of the patient appeared to require its more extended use, it could be administered orally. He combined this treatment with a preliminary dose of castor oil and the subsequent use of salines or calomel, preferably the latter. Thymol or calomel, or, better, a combination of the two, were most effective in assisting in the disappearance of the cysts from the stools, and in dealing with carriers. Quinine injections did not destroy the cysts. Thymol should be given finely powdered and in doses of 30 grains daily. Oils, alcohol, vinegar, butter and ghee, being solvents of the drug, should be excluded from the dietary. With regard to diet, he emphasized the importance of resting the inflamed gut as much as possible; this rest was best secured by a diet consisting solely of tepid albumin water and water. Milk should only be given if the tongue were clean. Malaria and scurvy were frequent complicating factors among the Indian patients, and required their appropriate treatments. It should also be borne in mind that typhoid fever might complicate or simulate dysentery, and might render the diagnosis difficult.

Captain KERR, R.A.M.C.(T.), said that of 661 cases of dysentery under his observation 27 had died. Twenty-four *post-mortem* examinations indicated that the infection was amoebic in 20 and bacillary in 4. The stools of 363 cases of suspected dysentery were examined, and in 312 cases amoebae or amoebic cysts were found. Roughly 50 to 60 per cent. of the cases were shown to be amoebic. The routine treatment in cases of suspected dysentery had been to give a course of emetine ($\frac{1}{2}$ grain morning and evening for six to ten days, according to the severity of the symptoms and the result obtained). In many cases an initial dose of castor oil or salts was given. Afterwards, when the blood and mucus had disappeared, the stools being still loose, the emetine was stopped and a drachm of a bismuth salt was administered three or four times daily until the diarrhoea ceased. At the end of two to four weeks 2 or 3 more grains of emetine were given, or powdered ipecacuanha was continued for a week or two. Throughout the treatment the bowel was occasionally cleared by magnesium sulphate or castor oil. In more urgent cases, with excessive purging, collapse and exhaustion, antidysenteric serum (20 c.cm., repeated two to five times) was combined with the emetine and proved very satisfactory in many cases. It was frequently found necessary to employ intravenous saline infusions in addition. He was quite convinced of the great value of emetine, and administered it in normal saline solution by the deep subcutaneous method. Since extreme exhaustion followed severe dysentery, and heart weakness was common, prolonged rest in bed was essential. He advised that such patients as had gone through a severe attack of amoebic dysentery should be prescribed a monthly course of emetine (1 grain for three or four days) for a few months as a preventive measure against liver abscess. He did not favour lavage of the large bowel; it had not proved satisfactory in his experience. Rectal flushing did, however, ease those cases in which thick mucus was an urgent symptom. Appendicostomy had been of benefit in one case.

Lieutenant Colonel A. H. LISTER, R.A.M.C.(T.), said that at the hospital with which he was connected every case of dysentery received a four days' course of emetine injections ($\frac{1}{2}$ to 1 grain twice daily). After four days' interval a second similar course was given. If all straining or bleeding had been relieved the emetine was then stopped. He spoke of the great efficiency of the drug. Antidysenteric serum was employed if no improvement followed the emetine, 40 c.cm. being given subcutaneously, followed by 20 c.cm. next day. It had proved of definite value in a few instances, but its results were not uniformly good. Perhaps the cases which reacted were bacillary in origin,

or the horse serum itself might have benefited the patients. Milk was excluded from the diet in acute cases, the substitutes being albumin water, whey, arrowroot, and barley water. It was thought advisable to exclude meat extract. Perhaps the outstanding feature in serious cases was vasomotor collapse, the systolic blood pressure falling to the seventies or even to the sixties in fatal cases. In some cases good results followed the subcutaneous infusion of one to one and a half pints of saline. Hypertonic saline infusions were more painful, and he was not sure that they were particularly advantageous. The infusion was combined with 10 minims of adrenalin solution (1 in 100) every four hours, injected hypodermically. Some cases were given brandy and champagne, some pituitary extract, some strychnine, but adrenalin appeared the most reliable. Pain was relieved by morphine and atropine given hypodermically. For tenesmus, after a dose of castor oil or enemata to empty the bowel of sloughs and debris, an enema of 3 or 4 oz. of warm olive oil containing a drachm of ichthyol was beneficial in some cases. An injection containing adrenalin and astringent was very successful in others. Castor oil (10 to 15 minims) or paraffin in half-ounce doses every few hours had been found of some service. For hiccup—*a sign frequently of fatal significance*—atropine had sometimes given temporary relief. For post-amoebic colitis bismuth and salicylates, astringents, chlorine water, and other antiseptics had been followed by uncertain results. Weak iodine, quinine, and silver preparations given by the bowel had only a qualified success. Careful dieting—for instance, the addition of curds or of soured milk, and of beaten-up eggs for the acute form, with the cautious trial of more solid foods, such as fresh fish or custard—was of real importance. Cereal soup might be of service. With this careful dieting, bismuth, liquid paraffin, and enemata of ichthyol and olive oil were used with favourable results. Many cases relapsed when taken off the special diet. When bleeding was serious adrenalin enemata, 1 drachm of the 1 in 1,000 solution to the half-pint of water, might be useful. Lime salts might be tried, and injection of horse serum seemed to have a good effect in exceptional cases. The possibility of a scorbutic element should not be forgotten. For the sequelae—asthenia, lassitude, backache, and tendency to recurrent diarrhoea—he was of opinion that convalescence would be hastened by change both of climate and of subjective outlook.

Major T. S. NOVIS, I.M.S., spoke of the value of 2-grain doses of ipecacuanha given every second hour with an equal quantity of tannic acid. He disagreed with the practice of giving 30 grains after a dose of opium, and the application of a mustard plaster to the epigastrium, because of its depressant effect and the continued vomiting it often produced. Intramuscular injections of emetine ($\frac{1}{2}$ grain) twice daily was the most successful treatment. He had seen very good results follow concentrated solutions of magnesium sulphate in cases presumably of bacillary dysentery, and in a few cases antidysenteric serum had been beneficial. The indications were rest and cleanliness of the bowel. The former could most nearly be obtained by starving the patient for two or three days and afterwards dieting with a food which left little residue. The bowel could be kept clean by large enemata of normal saline run in very slowly. Appendicostomy could scarcely be adopted for acute dysentery. Perforation was most frequent in the region of the caecum, and not uncommonly the extravasation became localized, necessitating drainage. After operation the edges of the wound might become gangrenous, a process which had been checked in a few cases by injection of emetine and the local application of carbolic acid. A course of emetine during or after convalescence would lessen the liability to hepatic abscess.

Captain F. OPPENHEIMER, R.A.M.C.(S.R.), had found that a very light diet was unsatisfactory. All but exceptional cases were put on such a diet as fresh milk, three eggs, custard, one pint of beef-tea, bovril or chicken broth, one pint of arrowroot or cornflour, clotted milk, cocoa for supper, and three lemons. The eggs were beaten up in the milk or, unless the patient were seriously ill, lightly boiled. Meat juices or extracts did not appear to aggravate the condition. After using sodium sulphate (3j hourly until a clear motion was obtained) he had abandoned it as

no improvement was observed and depression was caused. The practice was continued, however, in certain early bacillary cases. Enemata of quinine sulphate (1 in 2,000 to 1 in 500) had been used chiefly for the more severe amoebic cases. Such good results as had been obtained he attributed chiefly to their mechanical effect. When there was much tenesmus he usually followed this with a small starch and opium enema. He began by using emetine in half-grain doses twice daily for ten days. Since the amoebae did not always disappear from the stools he increased this period to fourteen days, using 1 grain daily in one dose. The results were very satisfactory. Later the course was increased to twenty-one days; three fatalities occurred. After intramuscular injections many cases had marked pain and stiffness two or three days later. From among about 3,000 injections about 30 cases had red and swollen arms, in one case a small slough formed, and in two suppuration occurred. *Ipecacuanha* had been used without favourable results as it was difficult to take effective steps to prevent vomiting. Quinine sulphate had been followed by some benefit in amoebic cases with a persistent high temperature, due to secondary infections of the colon. Dover's powders had been given freely at night to produce sleep and to relieve nocturnal diarrhoea. A stock mixture of bismuth, catechu and chalk had been used freely. For the griping pains he relied chiefly on hot fomentations and chlorodyne. The results obtained with serum in the bacillary cases had been good but not persistently so. Usually 50 to 100 c.cm. had been injected as an initial dose and followed by 40 c.cm. on alternate days for as long as appeared necessary. In the most severe cases the first dose was given intravenously. No ill effects had been observed. Intravenous hypertonic salines were very beneficial in collapsed cases.

Colonel TUBBY, A.M.S., thought that no surgeon could consider appendicectomy advisable during an attack of acute dysentery. He did not advise it in chronic dysentery; there was danger of peritonitis following, due to the lack of adhesions.

Lieutenant J. A. DELMEGE, R.A.M.C., gave a summary of observations on the treatment of 84 cases. Sixty per cent. were admitted during the second week of the disease, and 34 per cent. during the third week. Fifty per cent. were passing twenty motions in the twenty-four hours, with blood and mucus. For the remainder the average number of motions in the twenty-four hours was between eight and fifteen, with blood and mucus. All cases were treated with emetine intramuscularly ($\frac{1}{2}$ grain on the first day, then 1 grain on each successive day). Forty per cent. were so treated till the total dose was 15 grains; 60 per cent. until it was 4 grains. No difference in the general condition of the two sets of cases was observed. A few complained of dryness in the throat, and 5 per cent. had vomiting, necessitating the discontinuance of the drug. *Ipecacuanha* (5 grains) in powder, with 5 grains of Dover's powder was given to twenty-four patients after emetine had been omitted. Twenty of these patients vomited after each dose, and it was discontinued. Up to 40 c.cm. of antidysenteric serum were given in 15 cases: 2 improved, the result was doubtful in 3, no improvement followed in 8. Fifty per cent. of the cases were treated with emetine and bismuth salicylate (30 grains t.d.s.) and the remaining 50 per cent. with emetine and quinine sulphate (5 grains in tablet t.d.s.). No difference was noted between the two sets of cases. Morphine ($\frac{1}{4}$ grain sublingually) had proved most efficacious for abdominal pain. Tinct. chlorof. et morph. co., combined with bismuth, had been used for acute cases, and tinct. opii (m x), combined with astringents, for chronic cases, but in neither instance with noteworthy effect. Paraffin seemed to prevent the reappearance of streaks of blood in the stools, when used at the stage when the patient passed two or three hard motions in the twenty-four hours. He had been unable to convince himself that irrigations of potassium permanganate, followed in some cases by silver nitrate (30 grains to 3 pints of water), cut short the acute stage of the disease or prevented its chronicity. It soon became noticeable that cases kept on a low diet for a comparatively long period improved more rapidly than those whose food was increased more quickly. Roughly speaking, whole milk was not given till the patient passed only six motions or so a day with very little mucus, and bread-and-butter and

eggs were not added till he was passing three or four motions a day with little or no mucus.

Professor S. KARTULIS, after referring to the great prevalence of and high mortality from dysentery in Egypt before the discovery of its causation, spoke of the good results following the irrigation of the large bowel with a 0.5 per cent. solution of tannic acid. He testified to the very great value of emetine, but it often failed and sometimes did not act at all upon the living amoebae in the intestine, even in repeated doses. Perhaps in one-tenth of the cases treated by emetine the amoebae remained alive for a long time. He had not found that quinine injections into the cavities of liver abscesses was satisfactory. Afterwards the amoebae were found dead, but a few days later they appeared again in a living condition. An injection into the abscess of 0.5 per cent. of tannic acid also gave negative results. The same solution injected hypodermically proving also unsatisfactory he tried stronger solutions, and on three occasions used one of 20 per cent. The amoebae after three or four injections disappeared from the pus, and the abscesses soon healed. He had applied similar injections against amoebic dysentery itself, and found that the results were the same as those of emetine; the injections of tannic acid even proved effective when the emetine had failed. It was not always infallible, however. In 1913 he had examined the stools of about 80 cases treated by both methods, and on the whole the results were good. Further progress was made when he combined emetine injections with tannic acid enemata. The latter were constituted according to the formula: Tannic acid 4, iodoform 3, sodium chloride 6, arrowroot 25, aq. destillata 1,000; the mixture to be used in two enemata in the twenty-four hours. Oral medication was necessary to combat such symptoms as anorexia. His procedure was to inject at once $\frac{1}{2}$ grain of emetine intramuscularly, if possible, twice a day, and to order two enemata in twenty-four hours of this tannic iodoform mixture. The enemata must be kept in the large intestine for fifteen to twenty minutes. He only used purges such as castor oil or calomel in exceptional cases. The injections and enemata must be continued for three or four days. Usually severe symptoms disappeared on the fourth day, the patients becoming free from pain, tenesmus, and frequent motions with blood and mucus; amoebae were not to be found. Afterwards he continued for a week to inject the emetine and to employ the enemata once in every twenty-four hours. Two or three injections of emetine a week were given for another two weeks. For the first three days he permitted only small quantities of diluted milk in weak tea, or, better, slimy soups prepared with fresh butter. Two to four lemon drinks were allowed in the day. On the fourth day he added, once or twice a day, macaroni, rice, or arrowroot, well boiled in water, with fresh butter. Light, solid food was allowed after a week, but only if the stools were normal and free from amoebae. At the same time jams and marmalade might be given. In the early stages, when severe pain was present, he ordered linseed poultices to the abdomen and sometimes injected morphine. For diarrhoea he had used for the last three years, with excellent results, uzara in tabloid or liquid form. Two or three tabloids, or 20 minims of the liquid, should be given every two hours. He had treated by this method about 400 cases with no fatal result. The whole number of cases of amoebic dysentery treated by the old and new methods in the thirty-two years of his practice among private patients was about 3,000. Only four deaths had occurred, and these were treated by the old method.

Lieutenant H. CREAN called attention to the possible value of eusol as an injection into the bowel in certain cases. Eusol was a preparation which more than any other antiseptic was bactericidal without injuring the tissues, and it occurred to him that such a solution should be useful when the acutest stage was over and a secondary infection remained. The solution was made of equal parts of hot saline (2 per cent.) and normal eusol. The solution caused no pain. It had been usually given once a day for four days, and was retained for fifteen to forty-five minutes. Most of the cases reacted well, as shown by the reduction in the number of stools and the subsidence of the irregular fever. He recorded a case in which it appeared that a patient not previously exposed to infection

manifested the symptoms of dysentery forty hours after landing at Alexandria, and in whose stools amoebae were found.

Colonel GORDON HALL said that in the fatal cases which occurred after emetine he could see no evidence that emetine was the cause of death. The men died some days after the emetine had been withheld, and had had less emetine than many others. The death was probably due to post-dysenteric heart failure. Since the introduction of emetine there had been fewer cases of hepatic abscess, and even when this had commenced emetine could cure it. If emetine caused pain he considered that the technique was faulty.

Colonel C. W. HEALY referred to the three cases which had ended fatally from sudden heart failure after emetine had been employed. Two similar cases had been described by Dr. Milton Grendiropoulos. Emetine was a powerful agent whose dosage, and the length of time during which it should be administered, had to be considered carefully. The depressing effects of the drug, if given in 1-grain doses daily for some time, became very marked, the noticeable features being general lassitude, lowness of spirits, disinclination to make an effort, rapidity of pulse, loss of appetite, nausea, and in some cases difficulty in swallowing and a feeling of constriction about the throat and chest. The question of idiosyncrasy and the fact that symptoms of collapse appeared three or four days after the drug had been discontinued had to be considered. There could be little doubt that emetine, if administered continuously, depressed the heart, for the signs of cardiac depression improved quickly when the drug was omitted. Allan found that a 4-grain dose caused nausea. Baermann and Heensmain found that 2 to 2½-grain doses repeated led to weariness and loss of appetite, and that an intermission removed these symptoms. Colonel Healy suggested that the dose should be from ½ to ¾ grain daily, and that this should be continued until 5 grains had been given. The treatment should then be stopped for seven days, and might then be renewed if not contraindicated until 3 more grains had been given. When under emetine treatment patients should remain in bed, and an accurate record should be kept of the pulse-rate. If this definitely increased, the drug should be omitted until the heart resumed its normal condition. Convalescents who had received emetine should only be allowed up gradually, and should return to bed if the pulse-rate increased considerably. The diet should be fluid—albumin water, whey, milk and barley water or soda water, arrow-root at first thin and gradually thickened, and Benger's food. In severe cases the food should be given every two hours, about 4 oz. at a time, and neither hot nor cold. Milk diet was of the greatest benefit in chronic dysentery. Return to solid food should be made slowly. Fruit must be avoided for a long time.

Major HALL, R.A.M.C.(T.), gave details of the three fatal cases. One case was quite convalescent and had been up and walking for four days. He complained of a sensation in the throat; collapse appeared and death followed nineteen hours later. In neither of the others had there been any cause of alarm. *Post mortem* cardiac degeneration was found in all. The dysenteric ulcers were healed in two and healing in the third. As a routine ½ grain of emetine had been given twice daily for seven days; later, ¾ grain once daily. Second courses were given because of the continued presence of amoebae, and later still the drug was injected over long periods, with the idea of avoiding liver abscess. The symptoms noted were faintness, lassitude, tremor of muscles, and difficulty of swallowing in 3 or 4 cases and one of the fatal ones. There seemed no reason to suspect any particular variety of the drug. The amounts given in the fatal cases were 21 grains, 12½ grains, and 17 grains respectively. Symptoms arose respectively three, four, and four days after cessation of the drug. In 94 other cases 21 had had over 20 grains of the drug and 14 over 15 grains. In one case 28½ grains had been given. Of the 21 who had had over 20 grains 4 showed signs of cardiac weakness—rapidity of pulse, similarity of the cardiac sounds, and lack of the muscular element in the first sound. None showed "back pressure" symptoms. Emetine was obviously a protoplasmic poison, having a selective action on some forms of protoplasm, like quinine. He suggested that the

difficulty in swallowing and sensation about the throat might prove to be due to some change in the medullary nuclei, and advised general rules for the administration of emetine similar to those mentioned by Colonel Healy.

Surgeon-General BASTIE noted with satisfaction the unanimous opinion as to the value of emetine. If given with skill and care its risks became very small.

Notes on the subject were also submitted by Dr. C. EKINS, Lieutenant D. FORDE, and Lieutenant F. DUNN, R.A.M.C.

THE EAST AFRICAN CAMPAIGN.

We referred last week to some of the more important diseases which prevail in East Africa, and by which unacclimatized soldiers are very likely to be attacked unless they fully understand the nature of the precautions which ought to be taken. We are now able to announce that the Army Medical Department has prepared, for the use of soldiers, a pamphlet, entitled *How to Keep Fit in the African Tropics*, on the insect pests and diseases likely to be met with by an expeditionary force operating in British East Africa. It is a very excellent production, and cannot fail to be of the greatest use in the campaign.

The first part contains some brief geographical notes, and the second gives particulars of the climate of the various regions, which, as is well known, varies extremely, from most unhealthy tropical conditions to those prevailing in the highlands of East Africa, where the climate suits white men excellently. This part contains also a section on heatstroke and sunstroke, in which the irritating effect of even indirect sunlight on the bare skin is noted.

The next part gives a short account of the nature and habits of insect pests and the best methods of dealing with them. Particular attention is, of course, directed to the mosquito, to tsetse flies, and to ticks, but there are useful notes also on lice, and on bed-bugs and flies. As a precaution against lice the use of a powder made of naphthaline, iodoform, and creosote is recommended, which, dusted on the underclothing and rubbed between the seams of the coat and trousers, is said to have a marked preventive effect. One-third of an ounce is stated to be enough to clear the clothing of one soldier, but the treatment must be repeated once a week. "Crude oil emulsion," by which we understand an emulsion of crude petroleum oil with soft soap, is also recommended to be rubbed into the hair and on the insides of stockings, boots, or puttees, on the seams of clothing, and on the neck and wrists. As the proportion of soft soap is considerable it can be used when bathing and for washing clothes. It is also valuable against the bug and for washing furniture. It is added that bed-bugs may be prevented from climbing up by rubbing it on the legs of the bedstead. After a note on the common flea, particular attention is directed to the jigger flea, which lives in the sand of floors or dusty places where natives congregate; originally confined to America and the West Indies, it has spread to Africa and has now reached India. The soldier is recommended if he has an itch spot on the foot to show it at once to the nearest native servant. "If he nods and says 'jigger' give him a clean needle. The boys are usually very clever at removing the jigger, which is now like a little bag or bladder about the size of a small flea." Tobacco is very poisonous to these insects, and it is recommended to soak the boots and shoes in an infusion of native tobacco now and then.

The next section deals with diseases, including bowel complaints, fevers, and those due to worms.

Under the head of "fever" the first place is given to malaria, and the importance of remembering that most natives in a malarious country, and especially the children, carry the parasite in their blood, is mentioned. The importance of the daily prophylactic dose of quinine is well brought out, but though the value of the mosquito net is mentioned it is not much insisted on, and the soldier may be led to conclude that its use is impracticable. As we pointed out last week, the French and Belgian soldiers have learnt its value, and regard it as an indispensable part of their kit. We are inclined to believe that mosquito

net drill and mosquito net inspection should be matters of routine in all tropical campaigns.

Short notes on dengue and sandfly fever are followed by a longer note on tick fever. While it is true that it is best to prevent the fever by taking means to avoid being bitten by the tick, we do not altogether subscribe to the statement that no cure is known, for salvarsan is as effective in this disease as in syphilis, if not more so. The next section deals with sleeping sickness. Nyasaland sleeping sickness is distinguished as a separate form, due, it is strongly suspected, to *Glossina morsitans*, and it would have been well to have inserted a cross reference to the account of the nagana of animals, since the same insect is one of the flies which most commonly carries it, and its habits differ very much from those of *G. palpalis*, the carrier of the sleeping sickness of East Africa. The statement under the head of sleeping sickness, that lumps in the neck occur after the fever has developed, is too absolute; enlargement of the glands generally develops, but not invariably.

The diseases due to worms mentioned are those produced by ankylostoma, bilharzia, filaria, and guinea-worm. Finally there is a short section on diseases of animals, containing notes on "horse sickness," which also affects mules but not donkeys, due to some parasite as yet unidentified; on nagana, which affects not only horses and mules but also donkeys, oxen, and dogs, due to a trypanosome; and on the East Coast fever of cattle, due to a piroplasm carried by ticks, but chiefly by the common brown tick.

The pamphlet, as we have said, is generally most admirable, and if its recommendations are loyally carried out the effect on the health of the troops ought to be striking; but it must be recognized that while it is important that soldiers of all ranks should understand the dangers and the means of their prevention some of the most important directions can only be taken if the need for them is fully appreciated by general officers, staff officers, and commanding officers, including commandants of small detachments on special duty. For instance, the recommendations that in order to avoid heat-stroke in hot moist climates the men must march light, and not after a heavy meal, are matters entirely within the control of officers. It is a little unfortunate that the direction with regard to wearing coats and shirts open at the neck is ambiguously expressed. It is said that the cause of the condition of heat exhaustion is "want of evaporation from the skin; this is encouraged by moving about with coat and shirt open." It is, of course, the evaporation and not the heat exhaustion that is encouraged by wearing the clothes open. Another point is a recommendation that in malarious countries camps should never be made at the margin of small streams and lakes or pools. This, again, is a matter as to which the rank and file have commonly very little say.

HONOURS.

THE *London Gazette* of January 14th publishes a list of honours conferred on officers and men for services in the war, containing over 3,400 names, and filling three whole pages of the *Times*. The names of the medical officers in the list are given below. The list also contains the names of many non-commissioned officers and men of the R.A.M.C. and members of the military nursing services upon whom distinctions have been conferred.

C.B.

Surgeon-General R. W. Ford, D.S.O.

Colonels.

B. B. Grayfoot (I.M.S.).	W. C. Beevor, C.M.G.
J. Maher.	H. M. W. Gray (T.F.).

Assistant Surgeons.

W. J. S. Maine (I.S.M.D.).	E. H. Boilard (I.S.M.D.).
----------------------------	---------------------------

INDIAN ORDER OF MERIT, SECOND CLASS.

Subassistant Surgeons.

Ram Singh (1/4th Gurkhas).	Pargan Singh (6th Jats).
----------------------------	--------------------------

INDIAN DISTINGUISHED SERVICE MEDAL.

I.S.M.D.—Subassistant Surgeons Pohlo Ram (1/9th Gurkhas), Kishan Singh (113th Indian Field Ambulance), Mathura Parshad Sarswit (57th Wilde's Rifles).

SPECIAL PROMOTIONS.

Lieutenant-Colonels to be Brevet-Colonels.—A. J. Macnab (I.M.S.), J. M. Sloan, D.S.O.

Majors to be Brevet-Lieutenant-Colonels.—H. Boulton (I.M.S.), G. Browne (I.M.S.), F. G. FitzGerald.

Captains to be Brevet-Majors.—M. G. Dill, C. N. Draycott (T.F.), C. H. S. Frankau (T.F.), R. G. H. Tate.

Quartermasters and Honorary Lieutenants to be Honorary Captains.—M. Cohen (T.F.), C. H. Cooper, G. W. Harris (T.F.), J. Keogh (T.F.), J. H. Maunder (T.F.), H. C. Okill (T.F.).

OPERATIONS IN GERMAN NEW GUINEA.

On January 11th the Admiralty published an order upon the operations for the reduction of German New Guinea by a force from Australia, sixteen months ago, in the early days of the war. The D.S.O. was conferred upon Lieutenant T. A. Bond, of the Royal Australian Naval Reserve, and fourteen other officers were commended for services in action in the same operations. Among them was Captain Brian Colder Ampill Pockley, of the Australian Army Medical Corps, who, as recorded at the time, was killed in action.

CASUALTIES IN THE MEDICAL SERVICES.

Died of Wounds.

LIEUTENANT WILLIAM WILKIE DEANS, R.A.M.C., was reported in the casualty list published on January 13th as having died of wounds in the Mediterranean. He took the Scottish triple qualification in 1901, and received a temporary commission as Lieutenant in the R.A.M.C. on September 10th, 1914.

Wounded.

Lieutenant-Colonel G. A. Marshall, Australian Army Medical Corps (Dardanelles), May 6th (accidentally omitted at that time).

Lieutenant-Colonel W. Ranson, R.A.M.C. (T.F.), France.

Captain J. A. Sinton, I.M.S., Mesopotamia.

Lieutenant N. S. Joshi, I.M.S., Mesopotamia.

DEATHS AMONG SONS OF MEDICAL MEN.

Murray, J. B., Lieutenant-Commander R.N., third son of the late Dr. W. B. Murray, of Tarbury, Worcestershire, lost in H.M.S. *Natal*, blown up on December 30th.

Scott, A. G., Second Lieutenant 2/3rd Battalion Duke of Wellington's Regiment, elder son of Dr. G. H. Scott, of Sheffield.

NOTES.

THE COLONIAL MEDICAL SERVICES.

IN the article on the Medical Services in 1915, published in the JOURNAL of January 15th, it was inferred that the only colonial medical service which had officially served in the war was the West African medical staff. It should have been added that the East African medical services—those of British East Africa, Uganda, Northern Rhodesia, and Nyasaland—have also been concerned in the war, some of their members having been on service, though fortunately there have been no casualties. It might also be mentioned that the medical staff of General Botha's successful campaign in German South-West Africa consisted of South African medical men. They also, we think, escaped without casualties. But they do not belong to a colonial medical service; these services are employed in the Crown colonies only, not in the self-governing Dominions.

THE VALUE OF ANTITYPHOID INOCULATION.

The Research Defence Society issued a leaflet on protection against typhoid fever about fifteen months ago; it has now added a statement, dated January, 1916, in which it is reported as follows:

Among our Expeditionary Force in France and Belgium about 95 per cent. have been protected against typhoid fever, the annual average being about 90 per cent.

The annual admission ratio per 1,000 is more than nine times greater among the non-protected than among the protected. Among the non-protected it is 9.1 per 1,000. Among the protected it is 1 per 1,000. The death-ratio is thirty-one times greater. Among the non-protected it is 1.84 per 1,000. Among the protected it is 0.06 per 1,000.

The figures for Gallipoli have not yet been thoroughly analysed and criticized; but they leave no room to doubt the value of the protective treatment.

The addendum also deals with the suggestion that the statistics are worthless because typhoid fever and paratyphoid fever are often confused. The leaflet points out that this suggestion is false.

If the cases of paratyphoid fever are added to the cases of typhoid fever, the annual admission among the non-protected is 11.3 per 1,000. Among the protected it is 3 per 1,000. The death ratio among the non-protected is 1.90 per 1,000. Among the protected it is 0.09 per 1,000.

Copies of the leaflet can be obtained free of charge on application to the Honorary Secretary of the Research Defence Society, 21, Ladbroke Square, London, W.

INDIAN SOLDIERS' FUND.

Surgeon-General Sir R. Havelock Charles, G.C.V.O., Sir John Hewitt, G.C.S.I., and Mr. C. C. McLeod have gone to Egypt on behalf of the Indian Soldiers' Fund to see what additional

comforts and hospital equipment the Fund may properly supply for the benefit of Indian troops in that country. The hospitals for Indian troops at Brighton have been closed, but the Lady Hardinge Hospital at Brockenhurst will be continued for the present. We gave some account of this hospital last March (p. 438). It is well designed and well equipped, and has been admirably administered.

MEDICAL OFFICERS WANTED.

2nd Line Welsh Border Mounted Brigade.

Medical officers willing to serve abroad are required for this brigade. Pay and allowances as in regular army. Promotion to captain after six months' service. Applications to Lieutenant-Colonel D. C. Leyland Orton, S.M.O., 2nd Welsh Border Mounted Brigade, Morpeth.

2/1st South Wales Mounted Brigade.

A regimental medical officer is urgently required for a Yeomaniery regiment in this brigade now on the East Coast. Particulars may be obtained from the S.M.O., Head quarters, Yoxford, Suffolk.

England and Wales.

MEDICINE IN SOUTH WALES.

AT a meeting of the Board of Management of the Edward VII Hospital, Cardiff, last week Colonel Bruce Vaughan said that within the last seven years the hospital had received many princely donations, which had enabled it to provide a new wing containing 100 beds at a cost of £50,000, and a fund of £100,000 for their maintenance. The income of the hospital from invested funds during the period had been increased by £10,000 a year, but Colonel Bruce Vaughan accepted these great results as an encouragement to ask for more. The immediate needs of the hospital were, he said, in order of urgency: (1) An extension of the children's hospital; (2) addition of beds for eye cases; (3) the completion of the maternity department; (4) the provision of an orthopaedic department; (5) the provision of beds for male and female tuberculous patients for the purposes of observation and treatment; (6) the provision of extra surgical beds to meet the necessity of the waiting list; (7) an additional operating theatre; (8) the extension of the board-room, with separate rooms for study for the resident medical officers, and a chapel. At present there were 55 beds for children, and he suggested an addition of 25. He mentioned the fact brought out in a recent report by Dr. Newsholme, the medical officer of the Local Government Board, that Wales compared very unfavourably with England in regard to maternal mortality. With the full concurrence of the medical board it was desired to establish and equip maternity and child welfare departments. An orthopaedic department was also badly needed; four years ago something was done in this direction, but a well-organized department was necessary, with at least 14 beds and an operating room. It was desired also, in co-operation with the King Edward Memorial Association, to establish two wards for cases of tuberculosis—one for eight women and the other for ten men—where the cases could be thoroughly studied from the clinical, pathological, and bacteriological standpoints. Research must be undertaken, he said, jointly by the great hospitals and the medical schools, and this rendered all the more urgent the establishment on a proper footing of the Welsh National School of Medicine. The hospital was ready for it and Sir William James Thomas had provided money for complete modern laboratories, but, owing to the action of the Board of Education and the Treasury, the work had been delayed. The reason given was the necessity for reorganizing the University of Wales, but he did not consider that sufficient ground for hanging up a definite and much-needed scheme for the building of the medical school. Permission had been obtained to proceed with the erection of the physiological block, which would be completed early in the next year, but he called upon all men of influence in Wales to take their share in inducing the Treasury to remove its embargo on the establishment of a complete National School of Medicine for Wales. The appeal was supported by the Lord Mayor of Cardiff (Dr. R. J. Smith) and by Dr. Ewen Maclean, who said that the provision of a new maternity department would not only make the institution complete, but would serve the urgent need, day and night, of the whole community. It is announced that in response to the appeal an anonymous

gift of 10,000 guineas had been made, and that Sir William James Thomas has promised to equip the plaster room in the orthopaedic department as soon as it is established.

Scotland.

QUEEN'S NURSES.

THE twenty-seventh annual report of the council of the Scottish Branch of the Queen Victoria's Jubilee Institute for Nurses, which provides trained nurses for the sick poor in their own homes, states that the number on the roll is 413. There are 266 nursing associations in affiliation with the Scottish Branch, but the regular work of many districts has only been accomplished with great difficulty, and in some districts has had to be temporarily suspended owing to the fact that 147 nurses are on military duty; 90 are serving at home, 35 in France, Malta, Serbia, the Balkans, and Egypt, and others with Red Cross hospitals.

WAR AND INSANITY.

The annual report of Dr. Henry Carre, medical superintendent of the Glasgow District Mental Hospital, Woodilee, Lenzie, shows that the number of patients admitted (436), was greater than last year by 92 (69 males and 23 females). The increase, which is 117 over the average annual admission rate for the past ten years, is to some extent accounted for by the large number of senile cases admitted after Stobhill Hospital was taken over by the military authorities. The transference from Stobhill to Barnhill Hospital of the old people upset many of them so much that they had to be certified and sent to the two asylums under the Board. Dr. Carre states that as far as it is possible to determine there have only been 9 cases (4 males and 5 females) whose mental breakdown could be ascribed to circumstances occasioned by the war. Only one man was actually in the fighting line, one broke down in the excitement of mobilization, and two during military training. In the cases of five women the exciting cause of the mental breakdown was ascribed to anxiety regarding relatives in the fighting line.

THE WORK OF AN ABSENT M.O.H.

On account of the departure of Dr. G. Gray Buchanan, M.O.H. for East Lothian, on war service, Dr. Alexander Robb, Midlothian, has been appointed medical officer for the county *pro tem.*, with Dr. W. R. Martine, Haddington, and Dr. A. S. Miller, Trenant, as deputy medical officers for the western district of the county, and Dr. D. R. Macdonald, Dunbar, for the eastern district.

Correspondence.

THE CAUSE OF THE DIVULSIVE EFFECT OF PROJECTILES.

SIR,—Sir Anthony Bowlby's Bradshaw Lecture, published in your issue of December 25th, 1915, is most interesting and instructive. There is one statement, however, which admits of another explanation. Under the paragraph heading, "General Character of Gunshot Wounds," Sir Anthony says:

It has been shown that the injury caused by a bullet is largely due to the wave of compressed air which the bullet drives in front of it, and which expands within the tissues.

Can it be that compressed air is the cause of the "divulsive and expanding nature" of these wounds?

Professor Worthington demonstrated by means of photographs¹ every phase of the phenomena of a splash, from that of a drop of water into water to that of a modern projectile perforating modern armour plate.

Between the fluidity of an armour plate and that of water there are innumerable degrees. The human body as a whole represents one of these degrees, its several constituent tissues represent subdivisions of the degree. The ultra-instantaneous method of photography devised by Professor Worthington is necessary to secure permanent records of the splash of a drop of water falling into water, but a projectile striking an armour plate leaves a

permanent splash which differs in no essential from the water splash. A wound represents the "splash" caused by a projectile entering the human tissues. Professor Worthington's work appears to supply a perfect explanation of all the effects, both local and remote, which are the result of modern gunshot wounds.

There is the same tendency of the tissues to form "the bubble stage" of the splash. The thickened ring of up-raised tissues will follow Plateau's law and break or tend to break into fragments or "drops," explaining the "divulsive effect." The wound must be uneven, as a "rough" splash will be inevitable; a projectile or bullet may be of any size or shape: it may spin, wobble, or trip over itself at any velocity or angle, but the general phenomena at the moment the wound is being made will, considered generally, be the same; any stone thrown into any pond will convince of this—there will be details of "pattern" at the point of entrance of the stone, but the concentric waves will still travel to the confines of the pond. The microscopic appearances found at a distance from a wound compare with the effects of the concentric waves on the surface of the pond, or on an armour plate after a projectile has struck it.

The "concentric effects" of a projectile striking the forearm would not be found in, say, the rectus abdominis, but might conceivably be found in the deltoid of the same side. It would be interesting to know whether the "concentric effects" of a projectile wounding the forearm, when the whole arm is horizontally level with the shoulder, could be found in the deltoid of the opposite limb.

Towards the end of his lecture Sir Anthony instances blows on the abdomen which have produced grave internal injuries without any external wound. Surely not through the agency of compressed air?

Again, is the greater shock experienced when a limb is blown off high up due to the more intense action of the concentric waves because of the closer proximity of the centre of disturbance to the central nervous system?

Professor Worthington's photographs show that air follows a projectile, but does not precede it. This following column of air obeys Plateau's law, and breaks into bubbles the moment its length is greater than $3\frac{1}{2}$ times the diameter. This would imply a contracting of the column of air rather than a "divulsive and expanding force." Leaving the effects of sepsis out of consideration, there must be two kinds of sloughing in a wound—one very superficial, caused by the actual contact of the tissues with the projectile, the other deeper and more extensive, caused by the tendency of the thickened rim of the "bubble of the splash" to break into drops, because Plateau's law holds both for columns of air in liquid and for columns of liquid in air. The columns behave in this fashion whether vertically straight or circular and horizontal. If the projectile were perfectly spherical, perfectly smooth, and entered the body exactly at right angles, one would expect to find a ring of fairly even-sized regular tears round or in the wound; but as projectiles are never polished (in Professor Worthington's sense), never spherical, and rarely strike at right angles, the effects will always be different, but the wounds must present the characters associated with an internal explosion. When a stone is thrown into a pond, the drops of water which rise above the surface are not blown up by compressed air carried in either before or after the stone. The column of air dragged in after the stone breaks into bubbles, which rise gently to the surface.

The human body consisting of such different substances as muscle, bone, fat, fascia, nerves, brain, etc., all bound up in a tangled mass, would lead one to expect a very complicated and modified form of splash, just as happens when a stone is thrown into a pond, the surface of which is covered with floating and semi-submerged articles of different size and specific gravity.

The subject is full of interesting speculations, but Sir Anthony's compressed air theory reminds one of that other conjecture as to how many angels can stand on the point of a needle.

I venture to think a perusal of Professor Worthington's work would make the form of modern gunshot wounds more intelligible.

By the way, there is another book which will pass an idle hour at the present time—*Commentaries on the Surgery of the*

¹ A Study of Splashes. Longmans, Green. 1908.

War, by G. J. Guthrie, F.R.S., etc., President Royal College of Surgeons 1833, 1841, 1854, etc., covering the wars of the period 1808 to 1855. The treatment of wounds by chlorides of lime, soda, and zinc, hæmorrhage, sloughing, sepsis, gangrene, and every other accident or illness of the battlefield will be found there, as well as the same old grumbles at the War Office.—I am, etc.,

LIONEL F. WEST, M.R.C.S., L.R.C.P.

Birmingham, Jan. 14th.

SHERBURN HOSPITAL.

SIR,—Dr. Meachen is no doubt right in saying that there is an ancient hospital at Sherburn in Durham, and I accept his assertion that he is the physician-in-charge as conclusive evidence of its existence. I knew of his hospital, which is said by Dugdale to have been founded by Hugo de Puteaco, which I take to be the Latinized form of Hugh Pudsey, Bishop of Durham. It does not follow, however, that there was no leper house at Shireburn in Yorkshire, and Dr. Meachen admits that there was a hospital there, though he says it was not a leper house. He accuses me of spelling the name wrong, and says that my Shireburn in Yorkshire ought to have been Sherburn in Durham; but in the seventeenth century, when Dugdale wrote, people spelt according to their own fancy, and acknowledged no obligation to spell the same name always in the same way; and sometimes one, sometimes another, of these variants has been accepted and adopted. The place now called Sherborne in this county of Dorset was spelt by Dugdale Shireburne. I think, therefore, we may conclude that, while Dr. Meachen is right, I am not wrong; in fact, he is right, and I am right, and all is right as right can be.

Allow me in conclusion to thank you for your very handsome and interesting review of my lectures.—I am, etc.,

Parlstone, Dorset, Jan. 15th.

CHAS. A. MENCHER.

THE TONSILS.

SIR,—In the correspondence under this title it is accepted that, when there is any question of removing the tonsils, these glands should be removed *in toto*. The two points which are giving rise to discussion appear to be the following: (1) Is there any risk in carrying out complete enucleation of the tonsils in singers? (2) Should this enucleation be carried out by dissection or with the guillotine?

I have never had any complaint from a singer after this operation, for the very good reason that I have never ventured to perform it on a trained artist. With students of singing—those who are just "learning to sing," and in whom the operation is indicated—I have never seen any but satisfactory results, the improvement and development of the voice being sometimes very noticeable. But many other observers have had experiences which should put us on guard. Hudson Makuen thinks it is safer, in the case of singers, to leave the tonsil capsule, and possibly some portions of the tonsil.¹ Bryan D. Sheedy examined a series of one hundred throats, three to ten months after operation by the modern method of enucleation; about 5 per cent. of the patients complained of difficulty in using certain words, and had nasal intonation six months after operation. Four of the whole number had practically lost their singing voice.² It is, to say the least, unwise for any one with the necessarily limited experience of his individual practice with this operation amongst professional singers to stigmatize this possible risk as a "popular fallacy."

As to the method of operating: Enucleation of the tonsils by dissection, as I have seen it carried out by its chief exponent, is a neat and thorough operation, leaving the throat in a satisfactory condition. As evidence that I have no prejudice against it, I may point out that as long ago as 1901 I called attention to the inadequacy of the guillotine in certain cases of submerged and adherent tonsils, and recommended in such instances removal by dissection.³ Later on I learnt to use the guillotine to effect excision of the tonsil with its capsule by

using a tractor to draw both gland and capsule well through the ring of the guillotine. Specimens illustrating the completeness of this method were shown before the meeting of the British Medical Association in London in 1910, and are figured in my textbook. About the same time, as Dr. W. Hill has pointed out, Whillis and Pybus in this country and Sluder in America demonstrated that, instead of using traction, the tonsil and its entire capsule could be impressed through the guillotine ring by manipulation with the forefinger or by crowding the mass against the alveolar eminence of the lower jaw. No special "tonsillectomy guillotine" is required for this, as Dr. Syme appears to think. In my own clinic all tonsils are enucleated with the form of guillotine which was slightly modified by Mr. Charles Heath at the Throat Hospital more than twelve years ago. Until he left for the front, these enucleations at King's College Hospital were carried out rapidly, completely, and safely by my colleague, Mr. C. W. M. Hope, who formerly practised and advocated the dissection method. Many others have likewise discarded the method of dissection since learning that an equally good, if not better, operation can be executed with the guillotine. It is the method which is employed in many throat clinics in London and largely in America.

The correspondence columns are not the best place for studying and comparing the advantages and drawbacks of the two methods of enucleation. This can be done much better in our operating theatres and by demonstrations of patients and specimens before our medical societies. It is sufficient here to protest against Dr. W. S. Syme's statement, in regard to the removal of the tonsil complete in its capsule, that "to do this in every case some method of dissection is necessary." Enucleation of the tonsils by dissection is certainly not the only way. It has still to be shown that it is the safer, speedier, easier, or better way.—I am, etc.,

London, W., Jan. 17th.

STCLAIR THOMSON.

SIR,—All who have contributed to the discussion in your columns regarding the surgery of the tonsil are agreed as to the superiority of enucleation over the older methods, but there is some difference of opinion as to the technique of the operation. The following guiding principles may, therefore, be worthy of consideration. (1) In children the procedure introduced by Whillis and Pybus, that is, enucleation by means of the reversed guillotine, or, as I prefer to call it, the "new guillotine operation," gives uniformly good results. (2) In adults, and especially in those who have suffered from quinsy, firm adhesions bind the tonsil to its bed and render the above operation impossible. The ideal method for such cases consists in dissection with scissors and snare under local anaesthesia.—I am, etc.,

Edinburgh, Jan. 18th.

DOUGLAS GUTHRIE,
Lieutenant, R.A.M.C.

We cannot continue this correspondence.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on January 13th, when Sir W. Watson Cheyne, President, was in the chair.

Earlier Closure of the Library.

The Library will be closed at 6.30 p.m., instead of at 7 p.m., during the next three months. The Common Room will be closed during the war.

Contribution to British Red Cross Fund.

The Council recommended that the College should contribute 50 guineas to the funds of the Joint Committee of the British Red Cross Society and the Order of St. John.

Court of Examiners.

Mr. H. J. Waring was re-elected to the Court of Examiners.

Removal of a Member.

A member's name was removed, and a notice to this effect be sent to the Registrar of the General Medical Council.

Hunterian Oration for 1917.

Sir George Henry Makins was appointed to deliver the Oration for 1917.

Obituary.

HERBERT WILLIAMS, M.D.LOND.,

M.O.H. PORT OF LONDON.

WE regret to have to record the death, on January 16th, at the age of 53, of Dr. Herbert Williams, M.O.H. for the Port of London. He had recently been operated upon for appendicitis, and death was due to cardiac failure. He was the son of the late Alderman T. H. Williams of Weymouth, and received his medical education at St. Bartholomew's Hospital. He graduated M.B.Lond. with honours in medicine and physiology in 1888, and M.D. in 1890. He acted as assistant house-surgeon to the Metropolitan Hospital and house-physician to St. Bartholomew's. He was appointed assistant port medical officer (London) in 1892. In the following year he took the degree of M.D.Lond. in State Medicine and also the D.P.H. of Cambridge. In 1901 he succeeded Dr. W. H. Collingridge (who had been appointed medical officer to the City of London) as medical officer of health for the Port of London. The area under the jurisdiction of the Port of London Sanitary Committee extends from the high-water mark at Teddington Lock to Warden Point in the Isle of Sheppey, and includes the lower part of the Medway and innumerable streams, creeks, and harbours. One of the matters with which Dr. Williams had to deal was the possible danger of the introduction of plague, and it is stated that even to day the average number of rats killed every year is about 50,000. Among the duties to be discharged by the department over which Dr. Williams presided with so much ability, in addition to the inspection of ships for the prevention of exotic diseases, are the inspection of imported meat and foods generally, and of shellfish layings in the Thames estuary. He was also medical inspector under the Aliens Act and lecturer on port hygiene in the London School of Tropical Medicine. Dr. Williams was adjutant of the 1st Kent Royal Garrison Artillery Volunteers during the South African war, and afterwards held the rank of major in the corps. He was a man much given to outdoor sports, and was a good golfer and oarsman.

A life-long friend writes: By the death of Dr. Herbert Williams the profession has lost one of its most able experts in public health, and it is no exaggeration to say that the ability, tact, and energy he displayed during the fifteen years for which he occupied the important position of medical officer to the Port of London have rarely been excelled. Perhaps more than all others the Port of London involves powerful interests, many of which are more or less in conflict; but Herbert Williams possessed in such a high degree the qualities of firmness, tact, and a strong sense of justice, that he was generally able to carry out the sanitary regulations of the port to the satisfaction of all. The importance of his work as medical officer to the Port of London will be understood when it is stated that on him rested the duty of inspecting and passing, as fit for consumption, all the food brought to London by ships, in addition to that of preventing the ingress of contagious disease. Williams had a deep practical acquaintance with port conditions, combined with medical ability and a shrewd knowledge of mankind, and those who knew of these qualities were perfectly satisfied that the sanitary welfare of the great city was in safe and capable hands. Except to the few experts, his great work at the Port of London was almost unknown, for Herbert Williams had a contempt for self-advertisement. He knew his own worth, but was careless as to whether those outside the great Corporation he served were acquainted with his abilities. Those who knew him intimately will sadly miss his cheery personality, his capacity for forming firm friendships, and his high feeling for justice and right.

CHARLES HENRY FOX, M.D., F.R.C.P.E., M.R.C.S.,

FORMERLY OF BRISLINGTON HOUSE ASYLUM, BRISTOL.

WE record with regret the death of Dr. Charles Henry Fox, who died, aged 78, on Christmas Day at his residence in Edinburgh, to which he had retired after relinquishing practice at Brislington House, near Bristol. He was the

fourth son of the late Dr. Francis Ker Fox of Brislington Asylum, and a brother of the late Dr. Edward Long Fox of Bristol, and was born on June 7th, 1837.

Charles Henry Fox was educated at Shrewsbury and Highgate College, and entered at St. George's Hospital in 1855. He took the diploma of M.R.C.S. in 1859, and, after a further year at Edinburgh Medical School, he graduated M.D. at St. Andrews. He joined his father at Brislington House Asylum, and became a partner in 1873. He remained there until 1894, at first with his father and afterwards with his half-brother, Dr. Bonville Bradley Fox. When he relinquished practice he retired to Edinburgh, where he had many friends and old associations that he valued highly. He became a Fellow of the Royal College of Physicians of Edinburgh in 1900, and also a Fellow of the Botanical Society, and of the Society of Antiquarians of Scotland. He always described his earlier life in Edinburgh as his happiest year, and never regretted his return to that city to spend the last twenty-one years there, though for the last twelve years he had suffered from ill health, and had been a complete invalid for several years before he died. Ever courteous, kindly, and of a most generous and lovable disposition, he leaves behind him many relatives and friends who mourn his loss.

THE LATE COLONEL E. O. WIGHT, R.A.M.C.—A correspondent who was present sends us the following tribute to the memory of a dead comrade which was addressed to his officers by Colonel H. N. Thompson, D.S.O., at a recent fortnightly conference of the medical officers of an army corps serving in Belgium:

Brother officers, I ask you to rise while I remind you that this is our first meeting here since the passing of our brother Colonel E. O. Wight. I have no doubt that his striking personality and genial presence is vividly with you all at this moment, as it is with me. He was ever a loyal colleague and wise organizer and adviser. He possessed such wonderful energy that he had always been everywhere and seen everything throughout the division, and only spoke of what he knew. To those of you who had the great privilege of serving under him in the 49th Division he was the ideal chief, and I well know how he had won the affectionate respect—I may almost say reverence—of every one of you. Colonel White was proverbial in the corps as being a man devoid of fear, one devoted heart and soul to his work, and to the interest and care of the soldiers committed to his charge. He was an officer of the very best type which our corps produces, a conscientious worker, a good sportsman, and a gentleman to his finger tips. It was inconceivable that anything sordid or mean could ever find a place near him. In his career he set a bright example, and taught us how best a man should live, and, finally, how he best should die. I think his was the death which he would have most wished to die. Killed on the field of honour in the cause of his country and his King, the death most fitting such a gallant gentleman. *Requiescat in pace.*

WE regret to have to announce the death last week of Dr. EDWARD DANIEL O'NEILL, Resident Medical Superintendent of Limerick District Lunatic Asylum, after an illness which did not take an acute form until within a few days of his death. He was born sixty-three years ago. He was a student of the Carmichael School, Dublin; he took the diplomas of L.R.C.S. (1872), L.R.C.P. (1878), and M.R.C.P.I. (1884), and from 1881 to 1886 he was assistant medical superintendent at Richmond Lunatic Asylum, whence he was promoted to be resident medical superintendent of Castlebar Asylum, where he did duty for a period of four years. In 1890 he succeeded to the charge of Limerick Asylum, and during his long tenure of that office won the recognition of the inspectors, the committee of management, and the public for his thoughtful and capable administration and the kindness he showed towards the patients under his care. His death is greatly regretted, and the committee of management at its last meeting passed a vote of condolence with his family.

Dr. HENRY LAWRENCE, who died at Capetown on July 20th, at the age of 86, was the oldest member of the profession in South Africa. He was present at the first administration of chloroform in London, at University College, during an operation performed by Liston. He was born in England. He began his professional education as apprentice to a practitioner in a western county. In October, 1847, he entered at University College; he took the diplomas of M.R.C.S. and L.S.A. in 1850, and for three

years practised in London; he went to South Africa in 1854, and received an appointment in the Convict Department then mainly engaged in road making. Subsequently he practised for many years at George. He retired in 1880, and lived afterwards at Capetown. All Dr. Lawrence's four sons entered the medical profession. Dr. T. G. Lawrence, first in practice in George, went to Johannesburg in its early days and died in the Eighties. The remaining sons, Drs. Alfred, Norman (Major R.A.M.C.), and Arthur Lawrence, are still in the Cape Province. Two of Dr. Lawrence's grandsons are doctors—Dr. Ruthven Lawrence of Claremont, at present serving with the South African General Hospital in England, and Dr. Cyril Wilson, late Surgeon, R.N., more recently in practice in South Africa, and now serving with the Royal Army Medical Corps. The *South African Medical Record* describes Dr. Lawrence as a man of fine presence, who until lately retained all his vigour; only three years ago he underwent suprapubic lithotomy, and walked about, as though nothing had happened, within a fortnight. Dr. Lawrence was well read, as he never neglected general learning. His social qualities were high, and he charmed his friends by his conversational powers.

THE HON. WALTER HUMPHRIES MONTAGUE, M.D., of Winnipeg, died of apoplexy on November 15th. He was born at Adelaide, Ontario, in November, 1858, and was the son of a farmer. His career was remarkable; he began as an errand boy in a country store. He took a teacher's certificate at Woodstock College, and afterwards entered the Toronto School of Medicine, going from there to Victoria University, Cobourg, where he obtained his degree. He was admitted to the College of Surgeons and Physicians of Ontario, and to the Royal College of Physicians of Edinburgh. For several years Dr. Montague practised at Dunnville, Ontario. In 1883 he was an unsuccessful candidate for the Ontario legislature, and was first elected to the House of Commons in 1887. The election was voided, but he was re-elected the same year; that election was also voided by the Supreme Court of Canada. In 1889 he was an unsuccessful candidate at a by-election, which also was declared void, and in 1890 he was again elected. He was re-elected in 1891 and 1896, but was defeated in 1900. In December, 1894, Dr. Montague entered the Bowell administration without portfolio, and in 1895 became Minister of Agriculture, which office he retained under the Tupper Government until July, 1896. In 1908 Dr. Montague removed to Manitoba, and in 1913 was appointed Minister of Public Works. He retained that office until the resignation of the Roblin Government some months ago. Dr. Montague leaves a widow, two daughters, and two sons—Captain R. J. Montague, who is Staff Captain for General Ketchen, and Captain F. Montague, A.D.C. to General Turner.

The Services.

EXCHANGES DESIRED.

A CAPTAIN R.A.M.C. (T.F.) Field Ambulance, at present in England, wishes to exchange with an officer doing duty in a hospital or casualty clearing station. Address No. 350, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Captain (T.F.), at present serving in Mounted Brigade Field Ambulance at home, wishes to exchange with officer in Field Ambulance or Casualty Clearing Station abroad or about to proceed abroad. Address, No. 349, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

THE late Dr. J. W. N. Mackay, of Elgin, left personal estate of the total value of £13,269.

THE Police Commissioner of New York has taken action for the prevention of unnecessary noises, and has issued an order enjoining a strict enforcement of the regulations.

UNDER the presidency of Professor Sanarelli a national league for the hygienic well-being of soldiers in the field has been formed at Rome. Its object is to supply whatever is needed to make life in the trenches and fighting line generally more comfortable for the men, to improve their physical condition, and increase their power of resistance to disease. Branches of the league will be formed in different cities for the special purpose of arranging for the transmission of gifts for the troops.

Medical News.

THE *Journal de Médecine de Bordeaux* states that at the opening of the academic year 1914-15 there were still some students too young for military service, but the successive calling up of the 1915 and 1916 classes quickly thinned their already depleted ranks. At present Saint André, the principal clinical hospital, has only two residents; both are doctors of medicine, and one is a woman. Eleven externs are doing duty as residents. The other hospital workers (*stagiaires*) comprise a few young men medically unfit for military service with some women students and a sprinkling of foreigners. In the early months of the war there was a marked decrease in the number of ordinary patients. The total number for the third quarter of 1914 was 1,351. In 1915 the figures became almost normal; the number of patients in the third quarter was 1,883, higher by 532 than that for the corresponding period in 1914. A noteworthy point is the change in the nationality of the patients. Whereas before the war the wards were filled with Portuguese, Greeks, Dutchmen, Danes, and Norwegians, lying side by side with Moroccans come to Bordeaux to work on the quays, now their place has been taken by French men and women and by Belgian refugees. The scheme for uniting the four teaching hospitals—Saint André, the Children's Hospital, that of Le Tondu and the Pellegrin Hospice—into one vast general hospital, which was on the point of being carried into effect, has had to be held in abeyance till the end of the war.

IN some notes on insecticides published in the *Journal of Tropical Medicine and Hygiene*, Drs. Castellani and Jackson state that for use against lice on a large scale the best powder is naphthaline. It has a lower destructive action than kerosene oil, guaiacol, iodoform, or anise preparations, but has a less unpleasant odour than the first three named, and is much cheaper than the last. Of liquid insecticides kerosene appears to be the best. Where price is not a matter of consequence menthol powder is to be preferred to naphthaline; it not only repels lice and fleas, but mosquitos also. For bugs kerosene oil is the best insecticide, and next to it guaiacol and pyrethrum powder.

LAST February the *Field* published a very remarkable special supplement, written by Dr. Arthur Tacquin, Physician-in-Ordinary to the King of the Belgians, giving an account, with striking illustrations, of some of the deeds of the Germans in Belgium. The editor of the *Field* now announces that a special shilling number of that paper will be published on January 29th, giving a further account of the crimes of the Germany army. Among other matters it will deal with the murder of women and children, and the murder and wounding of civilians in France, with corroborative evidence from German sources; the use of civilians as screens, with German admissions that this had been done; and with the killing or mutilating of wounded, again with German admissions. The long preliminary table of contents, of which we have given only a brief outline, includes also outrages on the Red Cross and the poisoning of wells, and ends with the significant words, "more to follow."

THE China Inland Mission has issued a report by Dr. G. Whitfield Guinness (London: Morgan and Scott, 1915. Price 3d. net), of the medical work done in Kaifeng, the capital of Honan, under its auspices. The death (from typhus fever contracted in the course of his work) of Dr. Sidney Carr in 1914 made the running of the hospital there very difficult, but Dr. Guinness has since been joined by Drs. Jessie McDonald and D. M. Gibson. Medical training is carried on, and although Kaifeng Mission Hospital is not a medical school with power to grant a doctor's degree, the curriculum is a practical one and turns out men who are able to do a large number of operations with skill. These hospital assistants are divided into three classes: Student assistants, ward nurses, and ward coolies. The women's work is now under the charge of Dr. Jessie McDonald, who is a graduate of Toronto. In 1904, when the work was begun, there were 1,476 out-patients' attendances; in 1913 the number had risen to 15,021, and there had been a further increase in 1914. The number of in-patients in 1913 was over 600; and the 1,600 operations included 505 for enteritis, 175 for fistula in ano, 372 for various abscesses, 157 tooth extractions, and a few serious operative procedures. Local anaesthesia was used in 950 cases, no anaesthetic at all in 567, and chloroform in 133.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, *Antiology*, Westrand, London; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (advertisements, etc.), *Antiology*, Westrand, London; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish office of the *British Medical Association* is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

"TAX" has been assessed in respect of a temporary War Office appointment at the full—that is, unearned—rate of income tax, and inquires whether there is any right of appeal.

* * We presume that "Tax" refers to the year of assessment ending April next. The Finance (No. 2) Act, 1915, Sec. 29, abolishes the time limit for claiming the earned income relief, and though the date of the Act (December 23rd, 1915) is probably subsequent to the assessment, the Act refers to the whole of the taxation for the year 1915-16, and we think that the section quoted would enable our correspondent to lodge a claim to the relief now. He should communicate with the assessor or the surveyor of taxes, quoting the reference given above, and filing—if he has not already done so—a statement of his total income for the year. If the relief is still refused, he might be well advised to write to the Board of Inland Revenue, Somerset House, W.C.

"TEMPORARY OFFICER" inquires whether allowances from which the ordinary income tax has been deducted in the usual way are liable to super tax.

* * According to Section 66 (2) of the Finance (1909-10) Act, 1910, the "income" for purposes of super tax is to be "estimated in the same manner as the total income from all sources is estimated for the purposes of . . . abatements under the Income Tax Acts." It follows from this that income liable to income tax is also liable to super tax, but in the latter case the liability is in respect of the following year.

T. inquires as to the basis of calculation of (1) the statutory abatement, and (2) the allowance for cost of motor car, etc.

* * The amount of the abatement depends on the total taxable income. On the figures quoted, "T.'s" total income appears to be £400 earned plus £120 private income—that is, £520—and the abatement appropriate to the total is £100 on the new scale. With regard to the motor allowance, it has to be remembered that the cost of the original car or cycle represents capital outlay, and that it is only the expense of repairs, etc., and the ultimately inevitable "replacement" that are allowable. Apparently, no allowance is due in respect of the motor cycle, as no replacement cost has yet been incurred; on the other hand, an allowance is due for the renewal of the car, and it is understood that the amount due is taken by the officials concerned at the net cost of the original car—that is, £300, less £88 10s. allowed on purchase of the new car—provided that that sum is not less than the cost of the new car. It is, of course, assumed that no deduction has been made in the past by way of estimated depreciation allowance.

HERPES OF THE PENIS.

A CORRESPONDENT in the Far East reports an inveterate case of simple herpes localized to the right side of the body of the penis, which heals but recurs on the slightest irritation. Local applications, ionization, and drugs are without permanent benefit. Our correspondent asks if division, section, or stretching of the nerve supplying the affected part would be of service as similar treatment has proved efficacious in old-standing cases affecting the supraorbital region (Malcolm Morris, *Diseases of the Skin*, 5th ed., p. 179).

* * This case is apparently, as our correspondent implies, an instance of neuralgic herpes which not only affects the seat of eruption but is also felt along the nerves which supply the affected region. It is a form of zona or herpes zoster,

distinct from herpes of external origin (Gaucher and Marshall). Head and Campbell, who have enjoyed exceptional opportunities of investigating cases of herpes zoster in which death occurred from other causes, found that in common "shingles" there was always evidence of some lesion in a posterior spinal ganglion, while in instances in which the eruption appeared in the head the Gasserian or geniculate ganglia were involved. The lesion was usually a haemorrhage, but cancer and injury have also been noted (Norman Walker, *Introduction to Dermatology*). As these lesions lie so high up it is questionable if division of the involved nerve would effect a cure, and since, as our correspondent notes, branches of the ilio-inguinal nerve, as well as the dorsal nerve of the penis, are distributed over that organ, it would not be easy to determine in this case which nerve was at fault. The cause is certainly obscure. Norman Walker notes that prolonged dosing with arsenic predisposes patients to zona, as was proved in a celebrated beer-poisoning epidemic. Perhaps our correspondent's patient may, unawares, have taken food containing some poisonous element.

HIGH HEELS AND FLAT-FOOT.

"PES" asks for information or reference as to the effect of high-heeled boots or shoes in flat-foot. He thinks it difficult to defend the use of heels raised even moderately except on the ground of long-continued custom; but adds that although for a normal foot a boot with a high heel stands condemned under ordinary conditions, yet it is of course conceivable that it may be of service in the case of a foot already flat, or in one likely to be subjected to conditions favourable for the development of flat-foot. The mechanico-physical forces coming into action when the human body is in a state of balance in the upright position or during locomotion, or when the foot is turned in or turned out, as in "pigeon-toe" or "splay-foot," appear, he thinks, to be intricate.

ANSWERS.

A. R. B.—There are many excellent books on the subject, and our correspondent is recommended to consult the dean of his medical school.

PETROL DUTY.

LT.-COL. R. A. M. C.—The allowance for petrol duty is made by way of repayment or "rebate," and amounts to one-half of the duty. It is restricted to motor spirit used for a motor car kept by a duly qualified medical practitioner (and now also veterinary surgeon) "while it is being used by him for the purposes of his profession." The evident intention is to relieve the medical and veterinary professions as such, and if the uses to which our correspondent puts his car are not substantially different from those to which other non-medical military officers put their cars, we fear he may find considerable difficulty in making good the claim either to the motor spirit rebate or to the similar allowance of licence duty.

THE LUTETIN TEST.

MAJOR V. E. H. GATT will find a description of the technique and results of the lutetin test in the following works: Noguchi's *Serum Diagnosis of Syphilis*, third edition (J. B. Lippincott Co., London, 1912, price 12s. 6d. net). Marshall's *Syphilology and Venereal Disease*, third edition (London: Baillière, Tindall, and Cox, 1914, price 10s. 6d.). McDonagh's *Biology and Treatment of Venereal Diseases* (London: Harrison and Sons, 1915, price 25s.). Noguchi's original articles are in the *American Journal of Experimental Medicine*, 1909 and 1911. So far as we know, lutetin is not on the English market, but it might be obtained from Dr. Noguchi at the Rockefeller Institute for Medical Research, New York.

LETTERS, NOTES, ETC.

PARAFFIN IN DYSENTERY.

A CORRESPONDENT writes: I have advised, I need not say in an entirely friendly way, the use of refined paraffin in some cases of acquaintances returned home from Gallipoli suffering from dysentery and slowly convalescent. I prescribed a tablespoonful or less at bedtime in hot water or hot milk, and the results were extremely good.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

Observations ON TREATMENT OF GUNSHOT WOUNDS OF THE KNEE-JOINT.

BY
CAPTAIN A. L. LOCKWOOD, R.A.M.C.(T.C.).

WHILE the saving of the man's life is the most urgent consideration, the preservation of a useful limb ensures his position as a competitive wage earner, and relieves the State of an additional burden. Successful surgery of the knee-joint demands the soundest judgement and most skilled and particular attention to detail.

Injuries to the knee-joint have always obtained the greatest respect from surgeons—in fact, have been regarded with great dread. Surgery of the knee-joint has always been, and is still, a serious and anxious undertaking, but the treatment of wounds of the joint along the lines which I am going to describe has, in very great measure, reduced our dread of knee-joint infections.

In fact, the knee-joint responds most satisfactorily when treated fairly and rationally. No longer, in these circumstances, do we have great fear of death from sepsis, amputation is rare, ankylosis has been reduced to a minimum, and a movable, useful knee is, in a great majority of cases, obtained.

GENERAL PROCEDURE.

A man comes into a base hospital with a gunshot wound of, or about, the knee-joint. Almost before his clothes are removed his dressing applied in the field ambulance or casualty clearing station is taken off, and the joint examined with the following points in mind.

1. *Date of Injury.*—Usually from two to seven days previously.

2. *The Amount of Effusion about the Joint.*—Be careful to determine whether the effusion is into the joint or not. Practically every injury which either penetrates or bruises the synovial membrane produces a blood-stained effusion into the joint.

3. *The nature of the wound*, whether a tunnelling, perforating, or an open, penetrating wound, and the exact site of the entrance and exit wound.

4. *Temperature and Pulse.*—(a) Usually the temperature is from 99° to 101°, with a pulse from 80 to 100; (b) a temperature over 101° and a pulse varying from 90 to 120 implies an already purulent condition of the joint or a virulent infection.

5. *The Condition of the Leg Above and Below the Knee.*—(a) Presence of wounds or foreign bodies favouring a general septic condition of the leg; (b) whether fracture or not, into or close to the joint.

6. *The Probable Nature of the Projectile.*—(a) Hand or rifle grenade fragments; (b) shrapnel bullets; (c) distorted rifle bullets or shell fragments. The difference in the infective abilities of these are not great. Jagged rough metal acts as the best carrier of infective material. (d) Undistorted rifle bullets. In only a small percentage of cases does one find an acutely infected joint following a rifle bullet wound, especially if early immobilization has been secured, whether a tunnelling, perforating, or more open wound, even when the bullet is retained in the joint.

7. *The amount and kind of interference* there has been with the joint since he was wounded, such as the dangerous policy of placing tubes into the joint following the track of the foreign body for transit to base.

8. *The Patient's General Condition.*—One must be guided by the patient's ability to stand a long convalescence in determining the treatment of already seriously septic joints, especially where combined with fracture of the bones.

9. *Splinting.*—If the knee is not efficiently fixed in a splint, this should be done at once. In most cases a long gutter "fracture" splint (Jones) is quite sufficient until after operation.

Having determined these factors, if there is effusion into the joint, it is at once tapped, the fluid withdrawn, and, if

blood-stained or perceptibly purulent, 2 drachms of either 2 per cent. formaldehyde in glycerine (made up at least twelve hours before and not more than one week old), ether and iodoform, pure ether, or 5 per cent. saline are injected into the joint at once. A tunnelling wound produced by an undistorted rifle bullet usually requires nothing more except immobilization on a Thomas's splint. The joint must not be allowed to become tense from recurring effusion.

The fluid is sent at once for a bacteriological report from a slide and from culture.

The knee is bound on a pillow and at once screened or skigraphed in planes at right angles to each other. The patient is returned to his ward and prepared for immediate operation if an open wound is present.

An acute infective condition of the knee-joint demanding immediate operation usually presents the following:

1. Wounded from two to five days.
2. The joint is swollen, red, and tender. The patient complains of a throbbing pain in the joint.
3. Temperature not always high, usually varying between 99° and 101°.
4. Pulse usually rapid.
5. The effusion is blood-stained in about 96 per cent. of cases, and in about 56 per cent. perceptibly purulent.

METHOD OF OPERATION.

Preparation of Case.

The skin is carefully shaved for 6 in. to 7 in. above and below the knee, cleaned with petrol or ether, and painted with iodine. Omnopon and scopolamine, one full dose,* is given one hour before operation. The patient is sent to the theatre on a splint. Open ether is administered in preference to chloroform, so as not to increase any tendency to acidosis. In some cases the operation can be done under local anaesthesia. The splint is removed, and the knee-joint supported in a partially flexed position on a sandbag. The area is again painted with iodine.

Operation.

The first step is excision *in toto* of the wound or wounds down to the capsule. Then with another knife and forceps the capsule is excised and this knife and forceps at once discarded. Absolutely no necrotic tissue must be left. Further treatment depends on the conditions found.

A Tunnelling Wound: No Fracture.

After total excision, including the wound of the capsule unless effusion is exceptionally foul, and after having carefully removed all particles of dirt, cloth, etc., the cavity is thoroughly irrigated with 1 per cent. saline until all blood clot and pus is cleared out, the leg being very gently flexed and extended at the same time. The capsule is stitched up with fine catgut, care being taken not to leave a knot of catgut inside the joint. A small tube is left down just to, but not into, the capsule, and the tissues may possibly be stitched about it with fine catgut.

The skin is approximated with silkworm gut and a mastisol and gauze dressing (two layers of gauze stretched taut) applied. The skin is cleaned up thoroughly away from the site of the wound and the joint injected as before.

It does not make much difference which preparation is injected, but I prefer either the saline or the glycerine and formaldehyde, and of the two, the latter, because:

- (a) It is nearer the specific gravity of normal joint serum;
- (b) It is mildly antiseptic; and
- (c) Its mechanical oily nature seems more adaptable to a movable mechanism such as the knee-joint.

The knee is immobilized in slight flexion on a gutter splint and a Thomas's splint with slight extension. If the infection is confined to the front of the joint the extension should be omitted.

Open Penetrating Wound.

Such a wound with the foreign body still in the joint is treated in exactly the same way, except that the foreign body must be carefully localized beforehand, and removed with the minimum of trauma to the joint surfaces.

* Omnopon gr. 3, scopolamine gr. 1½.

A Wound with Localized Fracture of the Bones forming the Joint, with, possibly, the Foreign Body imbedded still in the Bone.

Such a wound is treated in exactly the same way, except that the foreign body and loose particles of bone and all soft and pulpy and possibly infected medulla must be carefully removed.

If there is much haemorrhage from the medulla, it is checked by packing the cavity with gauze wrung out of saline solution or with gauze and salt tablets.

If it involves the bone so that the capsule can be closed, this should be sutured so as to exclude the cavity in the bone from the joint. If at all possible, the synovial membrane should be closed. If it is not possible, the capsule should be carefully approximated as much as possible without tension and the wound packed with gauze and tablets, a small tube being left down just to the capsule. The plugging should be left in the bone at least five to eight days unless there are urgent reasons for removing it. The tube may be removed after two days if there is no effusion. The surface of the gauze pack and the skin around should be painted with iodine at least every second day. The superficial dressings should be changed daily at first, later only when soaked.

A Gunshot Wound of the Knee-joint where a Great Part of the Joint is Laid Open.

(a) If the patient's general condition will permit it at all, the wound is excised *in toto* exactly as in a small wound, irrigated, and possibly stitched up, leaving a small tube down to the capsule. It is preferable in all

FIG. 1.—The upper diagram shows the piece of drainage tube as cut, and the lower as bent for insertion in the wound.

such cases to leave two small tubes cut as shown in Fig. 1, which, if need be, act as a two-way catheter. In such cases it is particularly important to procure absolute fixation. If this is done, and the deep packing left *in situ* till loose, it usually happens that the rest of the joint does not become seriously infected.

(b) If the general condition is bad, temperature high (over 102°), pulse rapid (110 or over), the face flushed and anxious, complete arthrotomy, preferably subpatellar, is performed, both lateral ligaments, ligamenta mucosa, and the crucial

ligaments being also incised or cut away, and the semilunar cartilages removed.

The leg is supported, flexed to less than a right angle, on a pillow or backsplint, preferably on a splint of Captain Hepburn's type, and continuous irrigation with 5 per cent. saline started at once.

Barnard's method of draining the suprapatellar pouch and the two lateral pericondylar pouches, with their diverticula posteriorly, should never be used unless modified in the following way, when it may very rightly be tried, in the type of case in which pus of a very low degree of virulence is found in the joint, accompanied with slight rise of temperature, slow pulse, and a good general condition. In such cases tubes may be placed just down to the joint, but not traversing it. Where there is a tendency for the pus to collect in the suprapatellar pouch, a small tube about the size of a lead pencil may be inserted across the pouch, but all these tubes should be removed as early as possible.

Post-operative Treatment.—Where the small tubes are left just down to the capsule, they are wiped out or aspirated daily. The skin around the tubes is wiped with saline and then with iodine. With mastisol and gauze, the dressing is very much simplified. These tubes are removed if possible within the first forty-eight hours. The plugging is left in the cavity of the bone as long as possible until loose. Usually it can be left from five to eight days, and often longer. The joint is watched carefully for increasing effusion. If it tends to increase, and the temperature and pulse start to go up—

1. The joint is aspirated with a needle, and injected as before with the glycerine-formaldehyde, ether, or saline preparations.

2. If this be not sufficient, a large needle is inserted and the whole joint washed out with saline 1 per cent. till the saline returns clear.

3. If pus still persists in forming, two large needles

are inserted and saline is run continuously through the joint for from twelve to forty-eight hours, and repeated if necessary, care being taken not to admit air to the joint. The patient's general condition is carefully watched, as is also the area above and below the knee, lest pockets of pus form; support posteriorly by the "fracture" splint tends to prevent this. Especially are the popliteal space and the calf of the leg watched. Pressure on the large vessels and nerves about the knee is avoided. After arthrotomy continuous irrigation with 5 per cent. saline is used at first, then saline and glycerine dressing. The knee is closed down on a Thomas's splint with slight extension at the earliest moment, after the surfaces are covered with healthy granulation. If the component bones of the joint are badly comminuted, resection is performed, but it is not advisable to be in a hurry to do this until all signs of infection have cleared up, lest a fresh outburst be lighted up.

Amputation should be performed only as a last resort to save the life of the patient; then a quick circular operation should be done.

Sodium bicarbonate gr. xx every four hours and barley sugar *ad lib.* are given as routine where a septic condition may develop or is present.

SUMMARY.

The points on which I would lay most stress are:

1. That all foreign bodies, whether metal or loose bone, should be removed from the knee-joint at the earliest possible moment.
2. Perfect immobilization is absolutely necessary. Do not start passive movements too early; wait at least three weeks after the inflammation has subsided.
3. Absolutely complete excision of all necrotic or even oedematous tissue.
4. The capsule should be closed at the first operation if at all possible.
5. Antiseptics, other than the ones I have mentioned, should not be introduced into a joint.
6. Tubes should never traverse the joint surface as in Barnard's method.
7. Patients should not be moved till one is satisfied that infection has been successfully combated.

STATISTICS.

Space will not permit of complete tabulated statistics of all the cases treated in the last fifteen months, which I hope to publish later. I will simply give the results of 60 cases treated as described with what may be called the new method, and which remained entirely under my care until they were sent to England.

Death.

There was one death. In this case both the femur and tibia were badly comminuted, and the joint very purulent on admission. The patient was a cachectic, cadaverous-looking man, with no resistance, and he died in spite of early amputation.

Amputations.

There were three amputations. In two cases there was bad comminution of both tibia and femur, with the joint full of pus, and the general condition of the patient was not good on admission. In one case the amputation was done at once; in the other after five days in hospital. In the third case a hand grenade had absolutely shattered the joint and filled it with pieces of metal and dirt. Gas gangrene was present, and the leg was amputated at once.

Movement.

The results as to movement were as follows:

Ankylosis	3
Limited movement	4
Free movement	49

Fracture of one or both bones existed in 53 per cent., bloody effusion in 96 per cent., and pus perceptible to the naked eye in 56 per cent. of cases. The bacteriological reports on 42 cases showed that organisms were present in 76 per cent.

I wish to thank the nurses and officers that have assisted me during operations, and especially am I indebted to Colonel Gray, consulting surgeon, to whom the credit of the new method of treating gunshot wounds of the knee-joint is largely due, for his most valuable advice and assistance in these cases.

The notes of three cases of average severity with drawings made from the skiagrams are appended.

CASE I (FIGS. 2 AND 3).

Private M. Admitted June 3rd, 1915. Wounded four days before. On admission, temperature 100.1°, pulse 90. Knee-joint was very much distended with fluid, tender on pressure, and the patient complained of a continued throbbing pain through the joint. There was a jagged wound on the inner aspect of the knee-joint 2 in. above the articular surface of the internal condyle of the femur and on a plane about the middle of the condyle. On aspiration, the joint fluid was

FIG. 2.

FIG. 3.

deeply blood-stained. Bacteriological report was that *E. coli* and streptococci were found.

Operation.

June 4th. Temperature 100.7°; pulse 96. The wound was widely excised in a funnel-shaped manner down to the femur. The torn capsule was excised, and particles of khaki were found along the tract, even in the cavity of the femur. The hole in the condyle (about the middle of the internal condyle) was enlarged, the shrapnel bullet (distorted) removed, and all the soft, discoloured, and affected medulla removed, leaving a cavity about the size of a walnut. A double fracture was present in the internal condyle, extending into the joint, but it was fairly solid and the periosteum was intact, so the place was left. Thoroughly irrigated the joint cavity with 5 per cent. saline, sutured up the capsule with catgut, packed the cavity of bone with gauze and salt tablets, also the excised area in the tissues. Fixed a small two-way tube down just to the capsule; injected into the joint cavity 2 drachms of formaldehyde and glycerine and immobilized the leg on a Thomas's splint with a perforated zinc back piece in slight flexion and with a little extension. Packing in bone cavity was left eleven days. The packing in the tissues was left four days without changing, and then changed about every two or three days when soaked.

On June 6th the temperature was 99°, and the pulse 90. Passive movements started on July 2nd, and two days later the patient went to England with a perfectly movable joint.

CASE II (FIG. 4).

Private T. Admitted on May 27th, 1915. Wounded five days. On admission temperature 99°, pulse 80. A jagged entrance wound just below and external to the patella. The knee-joint was very much distended with fluid, and very painful and held in partial flexion.

FIG. 4.

The least movement elicited most severely the fluid was negative, but the effusion was deeply blood-stained.

Operation.

Local anaesthesia (novocain 1 per cent.) was used, administering only a whiff of ether when examining the articular surfaces. The wound was widely excised; the bullet carefully extracted with forceps; the joint thoroughly irrigated with 1 per cent. saline; the capsule and tissues sutured, leaving a small tube down to the capsule; 2 drachms of formaldehyde and glycerine were injected into the joint. The joint was immobilized on a

Thomas's splint, with a posterior gutter splint flexed at an angle against the knee and with slight extension.

On May 29th there was very little pain, the temperature was 99° and the pulse 78.

On June 15th passive movements started, and on June 20th the case was sent to England on a posterior gutter splint.

The result was a perfectly movable knee.

CASE III (FIGS. 5 AND 6).

Private C. Admitted on June 24th, 1915. Temperature 101°, pulse 96. Two small, dirty wounds of the knee, one externally, just above the head of the fibula, and the other in the middle

FIG. 5.

FIG. 6.

line in front, just above the tubercle of the tibia. The knee-joint was very much swollen, red, and very tender, and the patient complained of a continued throbbing pain through the joint. Bacteriological examination of the fluid showed (1) staphylococcus, (2) *B. coli*. The fluid was perceptibly purulent.

Operation.

June 25th. The temperature was 101° and the pulse 100. The wounds were excised widely. The fragments of shrapnel were carefully located and extracted with forceps. A narrow grooved fracture of the external articular surface of the tibia was present. The joint cavity was very distended with a reddish-yellow fluid.

The joint was thoroughly irrigated and the capsule stitched up. A tube was left down to the capsule externally and the tissues and skin sutured about it; 2 drachms of glycerine and formaldehyde were injected in the opposite side of the joint and the joint immobilized (with slight extension) on a Thomas's splint with a posterior gutter splint slightly flexed. The tube was removed on the second day.

On June 26th the temperature was 101° and the pulse 96, and on June 29th they were 99° and 88 respectively. Passive movements were started on July 15th, and the patient went to England on a posterior gutter splint on July 21st.

The result was a freely movable knee.

HEPBURN'S KNEE SPLINT (FIG. 7).

The black strips are of heavy aluminium splinting material, measured to approximately fit the patient's limb.

The shaded strips are of the lighter aluminium material.

The strip A B on each side is put on after the splint has been moulded to the desired angle.

An additional pair of supports applied at the joints C D will increase the rigidity.

Method of splicing D-B when long strips are not available.

FIG. 7.

A small pad is placed over the strap in the popliteal space and the splint is then padded in two sections, leaving the area of the joint freely exposed.

Pad (1) C, F, E, A, and (2) D, B, K, H, G, and cover with jaconet.

The splint is moulded to the leg and thigh, and firmly bandaged.

The foot is packed into the boot part with cotton-wool.

The patient may lie on the back or on either side, and the limb can be comfortably suspended from the point C, D, B.

This splint facilitates the care of the back and the use of the bed-pan.

The tools required to make the splint are a pair of pliers, a pair of heavy shears, and a hammer.

EPIDEMIC CEREBRO-SPINAL FEVER:

THE PLACE OF THE MENINGOCOCCUS IN ITS ETIOLOGY.*

By EDWARD C. HORT, F.R.C.P. EDIN.,

HONORARY PHYSICIAN TO AND DIRECTOR OF BACTERIOLOGICAL LABORATORY OF THE ADDINGTON PARK WAR HOSPITAL.

THE theory that the meningococcus of Weichselbaum is itself the primary infective agent in epidemic cerebro-spinal fever is one, as I have recently shown,¹ that rests on the slenderest evidence. Indeed, the only evidence worthy of the name is derived from the facts that the organism in question occurs in large numbers of acute cases of the disease and in primary and secondary contacts, that it sometimes will agglutinate with the human specific serum, and that recovery may follow the injection of animal antisera. Mere constancy of presence of an organism in any given disease or in contacts is, however, worth little as evidence of direct etiological relationship, as is universally admitted—for example, in the case of the *Streptococcus conglomeratus* of scarlet fever, of the *B. exanthematicus* of typhus fever, and of the bacillus of Hoffmann in convalescing diphtheritis. And agglutinability of an organism by a patient's serum does not sustain a thesis of etiological relationship of a direct kind, but only of pathogenicity, which may apply to secondary invaders as well as to primary. And, finally, the evidential value of the fact that recovery may follow injection of a specific antiserum is gravely impaired by the number of recoveries that take place without such injection, by the absence of control injections of normal serum, and by the repeated failures of specific serums such as were experienced in the late epidemic in this country. It is true that the failure of an antimeningococcal serum may be due to lack of identity of the strain of meningococcus supposed to be causing the individual case with the strain used in the preparation of the serum. There is no question but that there are numerous strains of genuine meningococci. But until better evidence can be produced in other directions that any single strain is capable of reproducing the disease in man, multiplicity of strains offers an unsatisfactory refuge for those who uphold the etiological claims of the meningococcus of Weichselbaum. And in this connexion it is not a little surprising that the disease has not yet been recorded to have been reproduced in any animal by injection of any strain, the production of meningitis in monkeys by intraspinal injection being of course worthless as evidence that the meningococcus is the cause of a disease in which meningitis is only an inconstant event.

Critical analysis, therefore, of the evidence—bacteriological, serological, and experimental—would appear to justify the statement that the primary cause of the disease epidemic cerebro-spinal fever is still unknown, the claims of the meningococcus not having been yet made good, and no rival having been yet established. This is the conclusion I came to in previous publications on the subject, and as a result of further research since then I am more than ever convinced of the accuracy of the statement referred to.

In thus exposing, however, the fragility of the claims of the meningococcus, I was careful only to state that its case was not proven. I did not assert that the meningococcus is not the cause of the disease, because I was not then in possession of experimental data which would justify so dogmatic a statement. Still less did I assert that the meningococcus does not bear an intimate, albeit unknown, relationship to the true infective agent. On the contrary, I insisted that the search for carriers of this organism should in no wise be abandoned, since whatever its relationship to the true infective agent ultimately proved to be the fact of the frequent presence of the meningococcus in acute cases, and in primary and secondary contacts, is as yet our main guide to efforts at epidemiological control.

To-day, however, as a result of an extensive series of

observations in monkeys, I am in a position to adduce experimental evidence which strongly suggests that the meningococcus is not itself the primary infective agent in epidemic cerebro-spinal fever.

This evidence is partly derived from the fact that of four monkeys injected intraperitoneally with living cultures of meningococci not a single animal appeared to be affected by the procedure. The largest counted dose given amounted to 9,200,000,000 organisms. In previously recorded animal experiments with living cultures of the meningococcus via other routes than the meningeal it appears that cultures on synthetic laboratory media have been employed. Owing to the possibility of rapid loss of pathogenicity on such media the absence of pathogenic response in the animals injected is not conclusive evidence that the meningococcus is not pathogenic as it occurs in the blood or cerebro-spinal fluid. In the experiments here cited, therefore, loss of pathogenicity was as far as possible excluded by cultivation of the organism in the cerebro-spinal fluid itself, care being also taken to inject the cultures in the fluid within the few hours after collection necessary to ensuring—by incubation—a sufficient degree of multiplication. As already stated, the results of injection of these four animals were completely negative, and this fact, coupled with the precautions taken only to inject the cultures under conditions approximating as closely as possible to those of cultivation in the body, appear to suggest the conclusion that the meningococcus, when injected intraperitoneally, is not pathogenic to monkeys. And the consequent deduction that this organism is not itself the primary cause in man of the disease cerebro-spinal fever is also suggested by the additional fact that intraperitoneal injection of the fresh filtrate (Chamberland F) from the cerebro-spinal fluid of two acute human cases of the disease produced in one of two further monkeys injected a continued fever lasting for several weeks, accompanied by a herpetic rash on the face, and in the second animal death forty-eight hours after injection, preceded by coma and well-marked retraction of the head. As will be seen in the protocols of the experiments here quoted, which are being published in full elsewhere,² conclusive evidence was not obtained that the disease had been reproduced in these two animals by injection of fresh cerebro-spinal fluid filtrate. But the results obtained were sufficiently striking to justify further experiments with fresh filtrates, and in the meanwhile to make it clear that the cerebro-spinal fluid of acute cases may contain a highly infective virus which is certainly not, in view of the first four experiments quoted, the meningococcus.

Trial was then made of the pathogenic effect in monkeys of the intraperitoneal injection of incubated filtrate (Chamberland F) of cerebro-spinal fluid, incubation being allowed to proceed for one night after filtration. A series of four monkeys were injected with incubated filtrates from four different cases, one of the animals receiving an injection of the same filtered cerebro-spinal fluid as caused before incubation continued fever in the animal referred to above. In all four animals in this series the filtrate injected was turbid with the organisms described below, but in no single case was the slightest pathogenic effect observed. These results suggest that the infectivity of freshly filtered cerebro-spinal fluid may be entirely destroyed by incubation at body temperature for a few hours, a fact which, as will be seen, may in the future prove to have a direct bearing on the question of metamorphosis, and on the problem of determining the true etiology of this disease.

The stage which we have so far reached in our inquiry may therefore be thus defined:

1. There is no good evidence that the meningococcus is the primary infective agent in the disease epidemic cerebro-spinal fever.
2. On the contrary, I have produced experimental evidence which suggests distinctly that it is not.
3. And I have also shown that the cerebro-spinal fluid of acute cases, when filtered through a Chamberland F bougie, may contain, when injected fresh, a highly infective virus.
4. This infective virus appears to be present as such only in the fresh cerebro-spinal fluid, incubation, on the other hand, appearing to destroy its infectivity.

If the meningococcus is not the primary infective agent it must, according to modern bacteriological conceptions,

* This paper is, to some extent, an abstract of a fuller paper on the same subject which will appear in the *Journal of the Royal Army Medical Corps*. For the compilation of this abstract and for the fuller paper, as well as for the filtration and animal experiments referred to, and for the hitherto unpublished experiments in typhus fever, I am alone responsible. For the strictly bacteriological observations referred to I share the responsibility with my colleagues, Dr. C. E. Lakin and Dr. T. H. C. Benians.

be either a secondary invader, or its presence must be symbiotically necessary to the true infective agent, or it must represent merely a phase in the life-history of the true infective agent. Apart from the further possibility that it may be a contaminant—a suggestion which can be summarily dismissed—it is difficult to imagine any other possible explanation of the rôle of the meningococcus of Weichselbaum. In order, therefore, to present a clear idea of the nature of the problem presented by the etiology of cerebro-spinal fever, it is necessary, before summarizing the results of our bacteriological studies up to date, briefly to discuss two of these rival theories, the third theory—that of symbiotic necessity—being merely speculative.

THE THEORY OF SECONDARY INVASION.

The term "secondary invader" is one that in diseases of uncertain etiology should be applied with the greatest care, however suitable it may be in the description of such organisms as are liable to invade the blood stream in grave systemic infections primarily caused by other organisms whose etiological claims are beyond dispute. The chief characteristic of these genuine secondary invaders is their diversity in, and inconstancy to, any given disease in which they appear, as all who constantly make blood cultures will agree. In the case, however, of certain infections—such as typhus fever, scarlet fever, and, perhaps, cerebro-spinal fever, to mention only three—the essential characteristics of the so-called secondary invader in each of these diseases is not their diversity or inconstancy, but their remarkable constancy. We have, for example, constantly occurring in all parts of the world the *Bacillus exanthematicus* in typhus fever, the *Streptococcus conglomeratus* in scarlet fever, and the meningococcus of Weichselbaum in cerebro-spinal meningitis. And, be it noted, it is not only the constancy with which, in these diseases, the individual organism occurs (in the individual disease) that arrests the attention, but it is also the restriction of this organism to that disease and to no other. For example, the *Bacillus exanthematicus* of typhus fever has never been described in scarlet fever, nor the meningococcus in typhus, nor the *Streptococcus conglomeratus* in cerebro-spinal fever. None the less, the names of these organisms and of the respective diseases in which they constantly occur are as household words. It has already been insisted that mere constancy of presence of one type of organism in any given disease is not adequate evidence that such organism is itself the primary infective agent in that disease. But this constancy of presence of the so-called secondary invader in the three diseases mentioned is too striking to be a matter of accident. It is therefore not unreasonable to insist that there may be both genuine and spurious secondary invaders, and that spurious secondary invaders may prove to be modified primary invaders. The assumption that an organism is a genuine secondary invader is, in fact, in the present state of our knowledge of the etiology of certain diseases, often no more legitimate than the assumption—which we have seen in the case of the meningococcus is not justified—that it is the primary invader. Since we have not sufficiently reliable evidence that the meningococcus is either the primary invader or a genuine secondary invader, formulation of the theory that this organism merely represents a phase in the life-history of the true causal agent of the disease, at present unknown, requires no apology. On the contrary, the facts of the constancy of presence of this organism in cerebro-spinal fever and its apparent inability to reproduce the disease in monkeys, or, indeed, to exert any pathogenic effect whatever when injected by the intraperitoneal route, establish an *a priori* claim to necessity for formulation of the theory and investigation of its truth.

THE THEORY THAT THE MENINGOCOCCUS MERELY REPRESENTS A PHASE IN THE LIFE HISTORY OF THE UNKNOWN CAUSAL AGENT OF THE DISEASE.

The theory—that certain bacteria may possess a more complicated life-history than their study under the artificial conditions of laboratory culture might lead one to suppose—was formulated by Hort³ in 1914 as a result of prolonged morphological and cultural study of the infective agent in typhus fever.

That certain protistic organisms, to use Professor Herbert Henry's apt word,⁴ exhibit multiple phases in the

course of their development, phases essentially characterized by morphological dissimilarity, has long been known in the protozoa. And in the intermediate zone between the bacteria and the protozoa evidence is gradually accumulating that, in the case, for example, of the infective granule-shedding spirochaetes, the same principle of diversity of developmental form is at work. There is therefore nothing unreasonable in my thesis that the meningococcus, which itself appears to be relatively innocuous, represents merely a phase in the life-history of an unknown organism which is only capable of reproducing the disease in its earliest phases. And provisional acceptance of this theoretical possibility is to some extent favoured by certain considerations which have never yet been satisfactorily explained.

Here, for example, are three facts which are quite unintelligible if we accept the Teutonic concept that the meningococcus of Weichselbaum is itself the cause of the disease.

1. That the incidence of the meningococcus in carriers varies inversely as the incidence of the disease in such carriers.

2. That the organism in acute cases is a constant inhabitant—in this disease and in no other—of a fluid which, as we have shown, appears to be only infective when the presence of no meningococci can be demonstrated.

3. That a relatively large non-motile organism, such as the meningococcus, with an average diameter of about 1 micron, must be itself capable of freely traversing the meningeal filter-bed. This fact is not disposed of by the suggestion that the meningococcus is carried to the spinal canal by leucocytes, since we have no proof that this is so, and the meningococcus is frequently found to be extra-cellular in freshly drawn cerebro-spinal fluid.

If, on the other hand, the meningococcus is merely a modified primary invader, a small but dangerous ancestor of unknown morphology having been replaced by a relatively large but innocuous descendant of known morphology, all these difficulties disappear. And in the case of such carriers as do fall victims to the disease one has only to suppose that virulent ancestors and harmless descendants exist side by side.

Attractive, however, as such a theory is, and unsatisfactory as the present theory upheld by the numerous followers of Weichselbaum has proved itself to be, the onus of proof rests on those who believe that certain bacteria do in fact exhibit different morphological phases of development associated with different phases of pathogenic activity. And in this connexion it is only fair to point out that I only applied it to the study of the etiology of cerebro-spinal fever after showing that it appeared to have a strong foundation in fact in typhus fever, though I have since found additional evidence in the case of scarlet fever and in streptococcal infections associated with cardiac disease. Before, therefore, summarizing such bacteriological evidence as I and my colleagues, Dr. Lakin and Dr. Benians, have been able to collect, which would appear to justify further study of the theory as applied to cerebro-spinal fever, it is necessary briefly to recapitulate the facts which originally justified formulation of the theory in the case of typhus fever. Such digression, though not at first sight germane to discussion of the problems presented by the etiology of cerebro-spinal fever, is really necessary in order to make intelligible the general line of inquiry we have pursued in the latter disease. And the fact that some of the ensuing observations on the bacteriology of typhus fever have not yet been published seems to justify their appearance here for the same reason.

COMPARISON OF THE PROBLEMS PRESENTED BY THE ETIOLOGY OF TYPHUS FEVER AND OF EPIDEMIC CEREBRO-SPINAL FEVER.

In typhus fever a pleomorphic organism, known as the *Bacillus exanthematicus*, can frequently be recovered from the body fluids of acute cases. In some epidemics, indeed, the organism has occurred so frequently as to suggest to many observers in the past that it was the true causal agent of the disease; and this belief was strengthened by the facts that it would often agglutinate, and even deviate

complement, in the presence of the specific human serum; that it was found in typhus fever and in no other disease, and that it was more or less pathogenic to guinea-pigs and mice. Unaccountably, however, the claims of this organism to be regarded as the primary infective agent never found general acceptance even by those who upheld the claims of the meningococcus in cerebro-spinal fever on even less satisfactory grounds. The *Bacillus exanthematicus*, in consequence, came to be looked upon as a genuine secondary invader, though no explanation was forthcoming as to why the organism occurred in typhus fever and in this disease only; and up to the year 1914 the general view of the etiology of the disease remained in this somewhat unsatisfactory condition.

In that year, however, it was shown by Hort and Ingram* that the *Bacillus exanthematicus* had little or no claim to being considered either the primary infective agent or a genuine secondary invader, inasmuch as they found by injection of the organism in monkeys that it was incapable of producing pathogenic effects in these animals. Their cultures were obtained by incubating human citrated blood from acute cases of the disease, the specimens of blood injected containing large numbers of the organism in question. On the other hand, injection of uninoculated specimens of blood from acute cases of the disease produced in several animals the typical disease which is generally accepted as the analogue of human typhus in monkeys. They had, therefore, in this last set of experiments, an excellent control which is at present lacking in cerebro-spinal fever. For example, I recently injected intraperitoneally each of three monkeys with 6 c.cm. of a 1 in 8 suspension in citrate solution of blood taken from three acute cases of cerebro-spinal fever without provoking any material reaction, and the same negative result followed the injection of three further monkeys with the same quantities of citrated blood after incubation.

This demonstration of the total absence of recognizable pathogenic effect after injection of monkeys with the *Bacillus exanthematicus* naturally raises the question—If this organism is neither the primary invader in typhus fever nor a genuine secondary invader, what is it? To answer that it is a contaminant is no more justifiable than would be the assertion that the meningococcus of Weichselbaum is a contaminant in cultures from cases of cerebro-spinal fever. If, however, the *Bacillus exanthematicus* is itself neither the primary invader nor a genuine secondary invader, nor yet a contaminant, the problem appears insoluble. And at the time the experiments cited were undertaken no explanation suggested itself. However, after prolonged morphological study of the bacterial content of typhus body fluids in the fresh condition, supplemented by morphological study of their content after incubation, followed by plating, some interesting facts emerged which offered a reasonable solution of the mystery, though, as will be seen, absolute proof of the correctness of this solution is a matter of great technical difficulty, and has not yet been obtained.

The facts referred to were these: In many cases it was found that in the fresh fluids the pleomorphic *Bacillus exanthematicus* was present in considerable numbers, especially in the urine, side by side with very minute organisms, many of which were near the vanishing point of vision. In other cases the fresh fluids, especially the urine and the cerebro-spinal fluid, were found to contain these minute organisms in what appeared to be pure culture. On the other hand, it was found that those fluids which contained, or appeared to contain, when fresh, these minute organisms in pure culture contained after incubation only the large pleomorphic organisms. Obviously, therefore, these small organisms, the discovery of which has since been amply confirmed by W. W. C. Topley,⁶ working in Serbia, had either disappeared or else had developed into the *Bacillus exanthematicus*. Attempts were therefore made to determine which was the correct explanation by filtration of the fresh fluids containing mixtures of the small and large organisms, in the hope that the small organisms would alone traverse the Berkefeld and Chamberland bougies employed. These experiments were successful to the extent that the clear filtrates on two occasions showed on centrifuging small numbers of the minute organisms alone, whilst incubation of the same filtrates produced in a few days marked turbidity due to the presence of large numbers of the *B. exanthematicus*. And pure cultures of these in some cases appeared on plating.

Unfortunately the minute organisms referred to would never survive subculture on plates beyond the first culture, so that biochemical identification was impossible. But single colonies, which appeared by film examination to be pure, on further subculture always developed the pleomorphic *Bacillus exanthematicus*. It was, however, impracticable to attempt to prove metamorphosis by growth from a single organism, either by Barber's method, or by the use of small fragments of coverslips, because in picking up—by the latter method—one minute organism near the vanishing point of vision it could not be guaranteed that another organism beyond the range of vision would not at the same time be taken up. Moreover, owing to the fact that in its earliest forms these minute organisms often appeared to have become detached from the periphery of zoogloecic masses of organisms so small as to be of quite indeterminate morphology the application of serological tests for purposes of identification with the *Bacillus exanthematicus* was also out of the question. Recourse was therefore had to injection of monkeys with pure first cultures of the minute organisms on serum-agar. The procedure was, in all the cases tested, followed by the appearance, after an incubation period of a few days, of a disease accompanied by continued fever. This disease, beyond being of a somewhat shorter duration, suggesting that full pathogenicity had been to some extent lost by artificial cultivation, had as much claim to be considered genuine typhus fever as the disease produced in monkeys by the injection of fresh human typhus blood. From two of the monkeys injected with fresh human blood minute organisms morphologically identical with the minute organisms described were again recovered, as well as the *Bacillus exanthematicus*. Two of the monkeys injected with the serum-agar cultures were—after recovery from the disease following injection—several months later injected with fresh human typhus blood, but neither animal responded, though one of the unimmunized controls exhibited a typical fever curve. These two animals were, therefore, perhaps immunized. A convenient opportunity of repeating this observation has, however, not yet occurred. A further interesting experiment bearing on the question of metamorphosis was, however, made. A series of four fresh specimens of human typhus blood collected before the crisis were injected into four healthy monkeys, and in three of the animals the so-called "typhus classique" appeared and ran its course. Another series of four specimens of human typhus blood in citrate, three of which were collected also before the crisis, was then injected into another series of four monkeys after the blood had been kept in the incubator at blood temperature for periods varying from several hours to several days, but in no case was any reaction whatever observed. It will be necessary to repeat this experiment, when opportunity allows, by injecting monkeys with samples of the same specimens of human typhus blood before and after incubation, in order to be certain that insusceptibility of the individual animal recording a negative result does not come into play. But, even as carried out, the experiment suggests that, as in the case of the cerebro-spinal fluid in cerebro-spinal fever referred to earlier in this abstract, it is only the fresh body-fluid which is infective. And in view of the other experiments referred to it is legitimate to suggest that the results of this experiment lend some support to the view that the *Bacillus exanthematicus* represents a harmless phase in the life-history of the minute pleomorphic organism described by Hort and Ingram in 1914. Before leaving the subject of typhus it is necessary briefly to refer to the *Bacillus exanthematicus* of Plötz, recent accounts of which appear at first sight to affect the validity of what has been said. The organism of Plötz, which has lately been exploited as the true primary infective agent in typhus, mainly differs from the *Bacillus exanthematicus* in the fact that it is said to be only possible to grow it anaerobically. Its claim to be the primary infective agent appears to be mainly based on the statement that it may produce fever when injected into animals, and that immunization can in this way be obtained against the fever-producing effect of injections of human typhus blood. It was with some interest, therefore, that I recently examined a heated emulsion of Plötz's *Bacillus exanthematicus*, large quantities of which have been tested as prophylactic vaccines in Serbia. The specimen received was contained in a sealed capsule, and

presumably it was looked upon as a pure culture of Plötz's Gram-positive pleomorphic organism, which is morphologically indistinguishable from a strain grown aerobically in this country. The contents of the capsule were centrifuged, and a film from the deposit was stained with Gram and counterstained with dilute fuchsin. Examination of the film revealed, however, that it was not a pure culture, and that mixed with the *Bacillus exanthematicus* were considerable numbers of the minute Gram-negative organisms morphologically similar to those described by Hort and Ingram. The Gram-positive bacillus measured in its greatest diameters from 0.5 to 1.5 microns, whilst the minute organisms varied from about 0.2 to 0.6 micron, though organisms nearer to the vanishing point of vision were also seen. It is, therefore, not an unfair inference that the infectivity of Plötz's organism, and its reputed immunizing properties, on which the claims on behalf of this organism have been largely based, are in reality due to the presence of the minute coccobacillary organisms described, and the value of the serological reactions reported is also impaired for the same reason. Final determination of these points can, of course, only be effected by examination of living cultures, which will be carried out as soon as opportunity for so doing occurs. But, in the meanwhile, the original observations carried out by Hort and Ingram in this country hold good.

With these observations in mind as regards typhus fever, the following notes on the bacterial content of the body fluids in cases of cerebro-spinal fluid now become intelligible.

THE TRUE BACTERIAL CONTENT OF THE INFECTED BODY FLUIDS IN ACUTE CASES OF CEREBRO-SPINAL FEVER.

The necessity of determining whether the meningococcus is or is not usually the sole inhabitant of importance of the infected body fluids in cerebro-spinal fever is, of course, an essential preliminary to attempting to determine if this organism is or is not biologically related to organisms other than the meningococcus. In other words, demonstration that the body fluids in this disease are commonly sterile—apart from the meningococcus—would go far towards disproving the theory that the meningococcus represents only a phase in the life-history of the true causal organism. On the other hand, demonstration that the constantly occurring meningococcus is only one of two or more types commonly infecting the body fluids in this disease would constitute a good case for inquiry, provided that the meningococcus was itself shown to be inert—as regards reproduction of the disease—and that the fluids originally containing it were in the fresh condition possessed of pathogenic properties. And both of these provisos we have shown to be fulfilled.

Before, however, recording the results of examination of the body fluids in cerebro-spinal fever it is necessary briefly to note that in order to determine the true bacterial content of any body fluid the ordinary method of judging of sterility by recording the results of inoculating laboratory media with these fluids in the fresh state or with their centrifuged deposits is often inaccurate. For example, as has recently been shown by Hort,⁷ neglect to incubate normal urine, before inoculation of the laboratory medium selected as an indicator of sterility or infection, often leads to serious fallacies. In the case of normal male urine, hitherto believed to have been proved to be sterile because in many cases no growth occurred on solid laboratory media inoculated with the fresh urine or its deposits, it was shown that if the specimens were first incubated not one out of 128 samples derived from several healthy individuals was in reality sterile. And control experiments done in parallel, in a small number of cases, completed the exposure of the fallacy involved by trusting to readings of the results obtained by inoculation of laboratory media with fresh urine. And it has since been shown by Hort and Ingram⁸ that in the case of the urine of subjects of systemic infections—such as lobar pneumonia, influenza, scarlet fever, mumps, measles, cerebro-spinal fever, infective endocarditis, typhus fever—and in convalescing urinary carriers of the enteric group, as shown by Hort,⁹ the same principle holds good. Similarly, in attempting to estimate the true bacterial content of the blood in any systemic infection, one is not justified in declaring the blood as sterile until examination has been made of laboratory media inoculated with

incubated blood, for which purpose suspension in solution of citrate or oxalate is better than defibrination, since loss may occur by entanglement in the fibrinous mesh produced by this procedure. And in all pathological cases, whether of urine or blood, it is always advisable to examine the fluids themselves after incubation as well as the laboratory media inoculated therefrom, as it sometimes happens that organisms will grow freely in the natural medium, but will resolutely decline to adapt themselves to the alien environment of a synthetic medium, even when a liquid medium is inoculated. And, finally, by application of this principle to the cerebro-spinal fluid in acute cases of cerebro-spinal fever, my colleagues and I found, as recorded in April, 1915, that not only may the meningococcus be missed if the ordinary routine be adopted, but also that it is in many cases impossible, otherwise than by incubation, to estimate the true bacterial content of specimens of cerebro-spinal fluid in this disease as regards organisms other than the meningococcus. These results, in so far as they concern the meningococcus, have since been amply confirmed by Captain Gaskell,¹⁰ working in Cambridge. It is, indeed, apparently the absence of this precaution of preliminary incubation which appears to be responsible for the number of specimens reported to be innocent of the meningococcus when in reality they are often not so, and, on the other hand, for the excessive attention which has in the past been paid to this organism as the reputed causal agent of the disease. In all cases, therefore, both for purposes of demonstration of the presence of the meningococcus and of determining what other organisms are likewise present in a given sample of this fluid, it is wise to make preliminary incubation a routine procedure—in parallel if desired—with the ordinary method.

SUMMARY OF BACTERIOLOGICAL EXAMINATION OF INFECTED BODY FLUIDS IN ACUTE CASES OF CEREBRO-SPINAL FEVER.

Full details of the results obtained by bacteriological examination of the specimens of infected body fluids we were able to obtain previous to April, 1915, are given in the two papers already referred to.

In the notes recorded in these papers reference is made to the examination of 10 specimens of cerebro-spinal fluid, 17 specimens of citrated blood, and 19 specimens of urine, several of which were catheter specimens.

Filtrates of these specimens were examined in five instances, the cerebro-spinal fluid supplying 1 filtrate, the blood 2 filtrates, and the urine 2 filtrates. In the case of the cerebro-spinal fluid, and in the case of one specimen of urine, two new Chamberland F bougies were employed. In the case of the two specimens of blood, and of the remaining specimen of urine, three new Berkefeld V bougies were employed. In numerous specimens of the unfiltered fluids submitted to complete examination the following organisms were described as occurring in the same specimens:

- (a) The meningococcus of Weichselbaum.
- (b) The meningobacillus (previously referred to by us as the "biscuit" bacillus).
- (c) Clusters of very minute organisms, sometimes diplococcal or diplobacillary in form, at other times of quite indeterminate morphology.
- (d) Jaeger's diplococcus.
- (e) Involution forms, diphtheroidal forms, and large bacillary forms.

The biochemical and cultural characteristics of the meningobacillus, which ferments the same sugars as the meningococcus, and of Jaeger's diplococcus are given in full in the protocols already published. In the case of the filtrates, whether the filter employed was a Berkefeld bougie or a Chamberland bougie, the results were the same, with the exception that the organisms which morphologically resembled the meningococcus were not submitted to identification tests.

These findings, in filtered and in unfiltered body fluids from acute cases of cerebro-spinal fever, were subsequently confirmed in their morphological details by five sets of workers independently of each other and of ourselves, as judged by their published papers.^{11 12 13 14 15}

From the occurrence of these several different types of organism in filtered and in unfiltered fluids, in many of

which from the application in parallel of the ordinary methods of examination without preliminary incubation the existence of pure cultures of the meningococcus was suggested, it was at first difficult to resist the conclusion that contamination must have occurred. And the presence of the involution forms, and of organisms of a diphtheroidal form, made this conclusion doubly difficult to resist. Increasing experience, however, of the value of preliminary incubation of the body fluids in cerebro-spinal fever before inoculation of laboratory media—in attempting to determine their true bacterial content—soon enabled us to refute the frequently made suggestion of contamination as being merely the outcome of inexperience of the method. And this conviction was greatly strengthened by finding that the same types of organisms simultaneously occurred again and again in increasing numbers of cases, and this largely irrespective of whether the fluid examined was cerebro-spinal fluid, blood, or urine. Moreover, the apparent existence of pleomorphism, although, as we have said, not absolutely proved by culture from single individuals, showed itself so constantly in subculturing from single colonies as practically to exclude the possibility of perpetually recurring contamination with the same organisms.

And, finally, the suggestion of contamination we have again found to be quite inadequate to explain the results obtained by repeating the observations with a fresh series of 18 specimens of cerebro-spinal fluid in the summer of 1915. Of these 18 specimens 6 were submitted to filtration, a new Chamberland bougie being in each case employed, and in the majority of the specimens, filtered and unfiltered, submitted to complete examination the same essential results were obtained, and may be seen by reference to the full paper now in the press. The total number of specimens examined amounts, therefore, to 64, of which 11 were filtrates, a Chamberland F filter being employed in 8.

The stage, therefore, we have now reached is this—that the true bacterial content of the body fluids in this disease is by no means adequately represented by the meningococcus. On the contrary—provided that these fluids are thoroughly examined by (1) study of the morphology of their deposits in fresh and in incubated specimens, both filtered and unfiltered; (2) supplemented, after plating, by cultural and biochemical study in, or on, laboratory media inoculated with incubated material, filtered and unfiltered; (3) injection of monkeys with the fresh filtrates—ample justification will be found for directly attacking the problem of the true ancestry of the meningococcus. And I therefore propose to make this the next stage in the investigation of the etiology of the disease side by side with further experimental observations in monkeys.

CONCLUSIONS.

1. There is at present available no adequate evidence to show that the meningococcus of Weichselbaum is itself the causal agent of the disease cerebro-spinal fever.
2. On the contrary, the experimental evidence here recorded distinctly suggests that it is not.
3. The fresh filtrate of cerebro-spinal fluid in the two cases examined contained a virus which was highly infective to monkeys.
4. The true bacterial content of the body fluids in this disease can only, as a routine procedure, be satisfactorily determined by, in the first instance, using the fluids themselves as the optimum medium of growth; combined with injection into suitable animals in the fresh condition.
5. Incubation of the body fluids, infective to monkeys in the unincubated state, appears to destroy their infectivity and, in so doing, to throw some light on the ancestry of the meningococcus.

INFLUENCE OF CONCLUSIONS ON THERAPEUTIC AND EPIDEMIOLOGICAL CONTROL OF THE DISEASE.

1. Although the meningococcus appears itself to be incapable of reproducing the disease, the search for and isolation of carriers of this organism should, for the present, be vigorously pursued as heretofore, since its presence is a valuable danger signal that the true infective agent is, or has been, present.
2. Attempts to prepare antiserums to the meningococcus, whether multiple strains are used or not, do not

appear likely to lead to effective therapeutic control of the disease.

3. Confirmation of the infectivity of fresh cerebro-spinal fluid would justify the preparation and trial of effective antiserums thereto in the treatment of the disease.

4. Attempts to destroy the meningococcus in the naso-pharynx of contact carriers, as a means of epidemiological control, would appear to be less valuable than an attempt to determine what the true infective agent of the disease really is.

5. In order to discover the true infective agent, whether biologically related to the meningococcus or not, further research is imperative, attention being particularly directed to filtrable organisms in the naso-pharynx and the cerebro-spinal fluid of acute cases.

STUDIES IN ANTISEPTICS (II) :

ON CHLORAMINE: ITS PREPARATION, PROPERTIES, AND USE.

BY

H. D. DAKIN, D.Sc., J. B. COHEN, F.R.S.,

AND

J. KENYON, D.Sc.,

THE UNIVERSITY OF LEEDS.

REFERENCE was made in a paper on the use of certain antiseptic substances for the treatment of infected wounds, recently published in this JOURNAL,¹ to a number of compounds containing chlorine linked to nitrogen and possessing strong germicidal properties. Substances containing this type of linkage were studied because analogous compounds were believed to be formed by the action of the actively germicidal hypochlorites upon proteins and some other nitrogenous cell constituents. After studying a very large number of substances of the type referred to, a selection has been made of the one which on the whole seemed to possess the greatest number of desirable properties and which experience showed to be practically useful. The substance chosen is para-toluene-sodium-sulphochloramide, and possesses the following structure:

The systematic name of this substance is somewhat unsuitable for general use, so that it has been decided to assign the more convenient name "chloramine" to the compound, thus indicating its membership in the group of substances containing the NCl linking. If, in future, other members of the group should come into use, it is suggested that the present compound should be known as chloramine-T to indicate its relationship with toluene.

Properties.

Chloramine, the preparation of which is described in a later section of this paper, is a white solid, crystallizing in prisms containing three molecules of water of crystallization. The solid has a very faint chlorous odour, while solutions of it are without smell. It is freely soluble in water, a saturated solution at room temperature containing

^{*} This investigation was carried out on behalf and with the support of the Medical Research Committee.

about 15 per cent. of the salt. It may be dissolved in two parts of boiling water. The aqueous solution reacts faintly alkaline and has a bitter taste. It is an extremely stable substance, and in solid form may be preserved indefinitely, while aqueous solutions show no significant decomposition after keeping for several months.

Chloramine has no corrosive action even in concentrated solutions. It neither precipitates nor coagulates proteins such as blood serum, a property which is of great practical importance in the treatment of infected wounds. Chloramine is practically non-toxic, guinea-pigs and rabbits tolerating as much as 1 gram per kilo given subcutaneously, with no symptoms other than a moderate local reaction due to the injection of a strong solution.

The germicidal action of chloramine is intense, and when tested against the ordinary organisms found in infected wounds it is found to be about as powerful as an equal weight of sodium hypochlorite. The molecular weight of chloramine is about four times that of sodium hypochlorite, so that the germicidal action of one molecule of chloramine is about four times as great as that of a molecule of sodium hypochlorite. In addition, it is much less irritating than the latter substance, and may be used safely at a concentration five to ten times as great.

Table showing the Germicidal Action of Chloramine on Several Common Organisms.

Two drops of a fresh culture of the organisms were suspended in 5 c.cm. of fluid, either water or 50 per cent. horse serum, and the antiseptic was allowed to act two hours at room temperature. In comparison, a few figures for sodium hypochlorite and phenol are added.

	Chloramine.	Sodium Hypochlorite.	Phenol.
Staphylococci in water ...	1: 500,000 - 1: 1,000,000 +	1: 500,000 - 1: 1,000,000 +	1: 250 - 1: 500 +

Complete sterilization is indicated by -, while + indicates that organisms survived.

Practical Uses.

Chloramine has already been used as an antiseptic for a variety of purposes with decidedly satisfactory results. It is not proposed at the moment to do more than outline some of its applications, leaving the detailed records of clinical results to others.

First of all a series of fresh but badly infected shell wounds containing dirt, clothing, and shell fragments were studied. The wounds were exposed, cleaned mechanically in the usual fashion, and lightly packed with gauze, leaving a narrow rubber tube or tubes passing to the bottom or recesses of the wounds. By means of these tubes 10 to 15 c.cm. of a 3 to 4 per cent. solution of chloramine was squirted at frequent intervals into the wounds by means of a glass syringe so as to moisten the whole surface of the cavity. The results were clinically similar to those observed in the early treatment of infected wounds with sodium hypochlorite,² with the exception that sloughs are dissolved somewhat more rapidly by the hypochlorite than by the chloramine. The majority of these wounds, though undoubtedly infected at the start, could be rendered aseptic after three to five days when treatment was commenced early. The wounds so treated were severe cases, including a number of fractures of the femur and humerus.

But the properties of chloramine seemed to indicate that it might find a more valuable application in cases where the more generally used antiseptics were either too irritating or too feeble. Accordingly it was used in a large number of cases of jaw and mouth injuries which are so apt to become extremely foul. Chloramine was used in 1 to 2 per cent. solution as a mouth wash, and a 2 per cent. solution was also squirted into the external wound cavities through short rubber tubes lightly sur-

rounded by gauze packing. The results were very encouraging. Some of these cases have been described by Surgeon Fisher, R.N., of H.M.H.S. *Reva*, in a recent issue of this JOURNAL. As an antiseptic mouth wash 1 to 2 per cent. chloramine has been found to be of value in a variety of septic mouth cases.

In addition chloramine at 0.5 per cent. has been used for the irrigation of bladder and uterus in septic cases and the results are stated to be encouraging. A few cases of chronic urethral infections which had been unsuccessfully treated with silver preparations did well with injections of 1 to 2 oz. of chloramine four times daily, beginning at 0.5 per cent. strength and then increasing later to 1.5 to 2 per cent.

A practical point which may prove to be of value is the fact that gauze may be readily impregnated with large quantities of chloramine. It is possible, for example, to get as much as 10 grams of chloramine in a four-fold roll of gauze 1 yard by 4 in. The use of this impregnated gauze for packing infected wounds is being investigated at the present time by Sir Berkeley Moynihan. There are very few substances of high antiseptic value which can be successfully used for impregnating gauze. Chloramine gauze obviously should not be moistened before use or the antiseptic will dissolve out. It can be used dry for lightly packing and subsequently moistened if necessary when in position.

Preparation and Cost.

Toluene-sodium-sulphochloramide (chloramine) was first prepared by Chattaway³ by the action of sodium hydroxide upon toluene sulpho-dichloramide, a substance obtained by the action of acetic acid on toluene sulphonamide dissolved in bleaching powder solution. A more economical method for its preparation consists in dissolving p-toluene sulphonamide (1 mol.) in a 5 per cent. cold alkaline solution of sodium hypochlorite (1.2 mol.), warming gently if necessary, filtering, and adding 1½ volumes of saturated brine. The chloramine crystallizes out of solution as a white shining meal of crystals, and is filtered off, washed with brine, and dried in the air.

The toluene sulphonamide necessary for the preparation is prepared by acting upon para-toluene sulphonic chloride with ammonium carbonate. The sulphonic chloride is a by-product in the manufacture of saccharin, and in ordinary times can be obtained very cheaply. But even when made directly from toluene, the finished chloramine should be a relatively cheap antiseptic, especially when its high germicidal action is considered. The cost of a 2 to 3 per cent. solution such as is commonly used should be considerably less than that of 10 volume hydrogen peroxide. It is anticipated that the manufacture of the substance on a commercial scale will be undertaken shortly by some British firm.

Mode of Action.

In its chemical and biological reactions chloramine closely resembles the hypochlorites in many respects. Its antiseptic action, while largely due to its contained chlorine, is not simply due to the liberation of sodium hypochlorite from the chloramine, for its antiseptic action is four times as great as that of the hypochlorite which could be obtained from it. It is believed that the antiseptic action of hypochlorites is due to their capacity for attacking proteins and related bodies, with formation of substances containing chlorine linked to nitrogen. Chloramine itself appears to act in the same way, for when brought into contact with proteins, such as blood serum, or with peptones or amino-acids, it parts with its chlorine, which attaches itself to the nitrogen of the second substance. With the simplest amino-acid, glycine, the reaction can be represented as follows:

In this particular case the chloramino-acetic acid formed is unstable, and breaks up to give formaldehyde and other products.

Practically, the matter may be stated as follows: Chloramine represents an active antiseptic containing a store of chemically combined chlorine in a form which is quite stable and non-irritating under ordinary circumstances. But when brought in contact with proteins and similar cell constituents containing basic (NH_2) groups, it acts as a chlorinating agent losing its chlorine to the basic

substances, and thereby exerting its antiseptic action as needed.

Chloramine, being a highly reactive substance, should not be mixed with other antiseptics. Both alcohol and hydrogen peroxide are decomposed by it.

GASSING ACCIDENTS FROM THE FUMES OF EXPLOSIVES.*

By LOUIS G. IRVINE, M.A., M.D. EDIN.,
JOHANNESBURG.

CASES of gas poisoning account every year for a good many deaths in the mines of the Rand, and for a considerably larger number of cases of temporary disablement and loss of working time.

The irritant acid fumes, commonly known as nitrous fumes, consist of a mixture of oxides of nitrogen. They belong to the group of respiratory irritant poisons in which chlorine, the vapours of bromine and ammonia, sulphuretted hydrogen and sulphurous acid, are also included. All of these cause, when inhaled, a somewhat similar train of symptoms. Fatal poisoning by nitrous fumes has occurred when persons have inhaled the acid fumes from a vessel containing nitric acid, which has been accidentally broken. In mines, poisoning from this source only occurs after the use of explosives in cases where the detonation has been imperfect, and particularly where burning of explosives has taken place. Nitric oxide (NO) is first formed, but this gas is rapidly oxidized, and nitrous fumes consist chiefly of nitrogen peroxide¹ (NO₂). This again quickly reacts with water vapour to form nitrous acid. What is actually inhaled is mainly a mixture of nitrous and nitric acids. Nitrous fumes are the red irritant fumes with the smell of which most miners are familiar. The smell is that of fuming nitric acid. The gas is intensely poisonous, and of all mine gases it is the most treacherous. We do not know the downward limit of its toxicity. Exposure to as little as 0.05 per cent. of nitric oxide for half an hour was found by Haldane to cause death in mice after about twenty-four hours, with the typical sequence of symptoms, and the symptoms were the same whether nitric oxide or the fumes of burning dynamite were added to the air. It was found that with small percentages of nitrous fumes the haemoglobin was normal at the time of death. With higher percentages (and more rapid death) the blood was found to be more or less chocolate coloured, and to contain methaemoglobin. Under the latter circumstances nitrous fumes act like carbon monoxide by disabling the haemoglobin, and may in concentration produce rapid death. Where the exposure is to small amounts death is due solely to the lung inflammation and its immediate consequences.³ It is with this latter form of poisoning that we are locally familiar. Half of the amount mentioned is the highest figure (0.026 per cent. reckoned as NO₂) found by Mann in mine air after blasting,² but the presence of the gas in poisonous amounts is probably not so very uncommon in ordinary blasting practice. I shall give some evidence for this statement later. What is certain is that quite a brief exposure to small quantities of nitrous fumes is sufficient to produce serious and even fatal poisoning. Air which contains enough nitrous fumes to cause feelings of irritation in the nose or air passages is very dangerous.

Dr. D. Macaulay was the first to direct attention to the important part played by nitrous fumes poisoning in gassing accidents on the Rand, and to give an adequate account of its symptoms and treatment.⁴

SYMPTOMS.

The symptoms of poisoning by nitrous fumes are very characteristic. At the moment of exposure they are slight. A man who inhales nitrous fumes has a sense of

irritation in the nose and throat, and of constriction, and perhaps pain, in the chest. There is headache, smarting of the eyes, and there is coughing. The latter is a characteristic sign. But these immediate irritant effects may not be severe, and commonly pass off altogether in a short time. The man may feel quite well and may continue work. He leaves the mine, has his supper perhaps, and goes to his room. Then, in from perhaps four to eight hours afterwards (very rarely later), acute symptoms suddenly come on, and progress with alarming rapidity. In a typical severe case there is marked and increasing distress in breathing, with coughing, and often severe pain in the chest. The cough is at first dry, and auscultation may at this stage reveal no moist sounds. But this condition is speedily followed by the expectoration of a copious frothy, rather fluid, blood-stained spit. The lungs become waterlogged, and auscultation now reveals copious moist sounds. There is cyanosis and marked dyspnoea and distress, followed, unless the case is promptly treated, and very often in spite of all treatment, by collapse, unconsciousness, and death within a few hours. Dr. Macaulay states that "the temperature is at first normal or subnormal, but, if the gas goes on for several hours, a rise takes place." I well remember the first case of this condition which I saw, now more than ten years ago. A miner was taken ill suddenly in his room on one of the mines at 11.30 p.m. I saw him at 1 a.m. He was cyanosed and in much distress. His lungs were full of moist sounds and one base was dull. The wooden floor of his room was covered with a blood-stained fluid expectoration. He died at 5 a.m. I could not reconcile his condition with that of any form of acute pneumonia which I have seen, but it agreed at every point with the published descriptions of nitrous fumes poisoning. It is probable, I think, that a certain number of cases returned as "pneumonia" amongst underground workers are really cases of nitrous fumes poisoning.

The typical sequence of symptoms in nitrous fumes poisoning is therefore this:

1. Initial symptoms of irritation occurring at the moment of exposure and usually comparatively slight. Nitrous fumes never, in our experience of ordinary gassing accidents, produce partial or complete unconsciousness at the time of exposure, as does carbon monoxide, although they may do so if present in massive amounts, and cases of rapid death from the concentrated fumes of burning explosives may be partly due to this cause.

2. A latent period of several hours' duration, during which the patient may and commonly does feel quite well.

3. The sudden onset after that interval of acute symptoms, due to a rapidly progressive inflammatory oedema of the lungs. The appearance of this well marked symptom sequence is of great diagnostic significance.

The post-mortem signs are also definite. There is an intense injection of the trachea and bronchi, which is characteristic. The lungs are intensely oedematous, often enlarged and tense with oedema. A copious frothy, blood-stained fluid exudes from them on section, and may be seen to occupy the air passages. There may be patches of incomplete consolidation, subpleural haemorrhages may be observed, and blood-stained fluid in the pleural cavities or the pericardium. The right heart and the great thoracic and abdominal veins are engorged with dark, thick, sometimes almost tarry, blood. The abdominal veins especially are often very greatly distended.⁴

There is one other point. Miners from time to time complain that after slight exposure to blasting fumes—perhaps from blasting at some distance from their working place—they are attacked the same night with difficulty of breathing, and perhaps slight spitting of blood, which pass off in a few hours. The affected man thinks he has had an attack of "asthma" or "bronchitis." He has really had a slight attack of nitrous fumes poisoning. The most sedulous care must be taken that, if any casual blasting has to take place before the end of the shift, the water blast shall be invariably employed immediately after, and that the fumes are thoroughly dispersed. Precautions must be taken, also, in the general blasting at the end of the shift, in order to obviate the risk of inhalation of drifting fumes of this dangerous gas by men waiting on the stations before being "hailed" up the shaft.⁵

Finally, I may state that the intensely irritating character of nitrous fumes has suggested that the repeated

* Extracts from a paper on accidents from poisonous or asphyxiating gases in mines, dealing generally with the subject, and also with the organization of the use of rescue appliances in mines, read before the Witwatersrand Branch of the British Medical Association, and published in full in the *Medical Journal of South Africa*.

inhalation of small quantities of this gas may, by maintaining a catarrhal condition of the air passages and lungs, be a contributory factor in the development of miner's phthisis.

The accidents under review fall into two groups: A. Those due to exposure to the fumes of explosives after blasting — the ordinary "gassing" accidents. B. Those due to explosives being accidentally set on fire and burned.

A. ACCIDENTS CAUSED BY THE FUMES OF EXPLOSIVES AFTER BLASTING.

I found it desirable to subdivide this group into two classes:

1. Cases in which the Exposure was Immediately or Shortly After Blasting.

These accidents occurred when persons returned too soon to the working places after blasting, or where they were affected by the fumes of explosives arising from blasting taking place in other parts of the workings. I found that in such cases either carbon monoxide or nitrous fumes poisoning might result, but that the latter type was considerably more common.

Whether the one type of poisoning or the other occurs under these circumstances is due in part to the character of the explosion, since if definite partial burning of the explosive takes place the risk of nitrous fumes poisoning is especially great. But the result will depend also on the duration of exposure. Unless carbon monoxide is present in large amounts, it takes time to produce its effects. On the other hand, the records abundantly show that quite a brief exposure to even small quantities of nitrous fumes is sufficient to produce serious or fatal poisoning from this source.

For the same reason drifting fumes from blasting will typically cause nitrous fumes poisoning, and persons may be "gassed" in this way by the fumes from blasting which has taken place at some considerable distance. Sometimes one or more of a party working in close proximity may be affected, while others escape.

Mixed poisoning must sometimes occur, but the number in which the evidence points to the probability of such a conjunction is surprisingly small. One or other type is almost invariably markedly predominant. I know of no case in which a man who had been rendered unconscious by carbon monoxide and had then recovered, developed later on signs of nitrous fumes poisoning. On the other hand, it is probable that carbon monoxide may co-operate in some cases of nitrous fumes poisoning in aggravating and prolonging the initial symptoms.

Another interesting point is this: It appears from the evidence that the danger from nitrous fumes exists only for a comparatively short time, perhaps an hour or so, after blasting. The longest interval observed between the occurrence of blasting and the occurrence of exposure, in this type of poisoning, was two hours, and this was exceptional. This circumstance, I would suggest, is probably due to the fact that nitrous fumes are very soluble in water, and that mine air is always highly charged with moisture, and also to the circumstance that these fumes are not often present in large quantity after blasting.

Let me now quote a few typical instances of accidents of this sort. These will suffice to indicate the circumstances in which these emergencies occur, and the general nature of the evidence on which I have relied. Some are drawn from the cases originally investigated, some were of more recent occurrence.*

CASE I.—Exposure Immediately After Blasting: Poisoning by Nitrous Fumes: Three Deaths.

The following interesting case was described by Dr. D. Macaulay. It was amongst the first in which the part played by nitrous fumes poisoning in gassing accidents was clearly recognized.

Two white men and three natives were working at the end of a drive, with a crosscut leading off it about a hundred feet from the face. The miners in the crosscut blasted at 3 p.m., before the party in the drive had left, and without giving them warning. The latter were imprisoned in the end of the drive for three-quarters of an hour. They felt that they were being gassed and turned on the compressed air. When the smoke had cleared they left the drive and went to the surface. The white men washed, changed, had their evening meal, and went

to their quarters. Acute symptoms of respiratory distress came on in both at 10.30 p.m., and when seen by Dr. Macaulay at 11 p.m. they were so ill that doubt was entertained by him whether it was possible to move them to the mine hospital a few hundred yards away. Both eventually recovered under energetic treatment. Nothing was reported at the time regarding the natives. They went as usual to the compound and did not report sick. Next morning one was found to be dead and another moribund. The third was very seriously ill, and he also eventually succumbed.

A post-mortem examination on these natives, made by Dr. Macaulay, at which I had the opportunity of being present, showed the typical signs of acute inflammatory oedema of the lungs, and great engorgement of the heart and venous system with dark blood.

CASE II.—Exposure Immediately After Blasting: Poisoning predominantly by Nitrous Fumes: One Death.

A white miner blasted the cut in the face of a drive. He did not use the water blast. He then returned with two natives to charge and blast the round, turning on the compressed air when doing so. As three holes of the round did not explode (there was therefore probably imperfect detonation and partial burning), he returned a second time to refire them. The natives stated that both times they returned "the smoke was too thick," and one failed to reach the face the second time. The white man did not say anything, but they saw that he was affected by the smoke. All left the mine together, apparently at 8 o'clock or a little after. The white miner felt ill on arriving at the surface, and waited for some hours in the change house. Afterwards he set out to walk home, then he telephoned for a cab. He walked from the cab into his house, reaching the latter after midnight. The medical officer of the mine was sent for to see him at 1.30 a.m., and found him "suffering from the effects of gassing usually ascribed to nitrous fumes." The man was too ill to be moved to hospital. He died at 2 p.m. the following day.

This case is an amazing example of a man throwing away his life, through sheer recklessness and contempt of the regulations which govern, or should govern, blasting operations.

In this case the prolonged character of the initial symptoms suggest a mixed poisoning, and the circumstances of the accident render this probable. The later symptoms were typical of nitrous fumes poisoning.

Post mortem the lungs were found to be tense ("ballooned") and oedematous.

The district surgeon, Dr. T. B. Gilchrist, states that the blood was somewhat chocolate coloured, but that after an hour's exposure to the air it became more red. No carboxyhaemoglobin was found in the blood.

2. Exposure Delayed until Several Hours After Blasting.

These cases occurred when the working places were entered on the following shift. They were caused by the stagnation of blasting fumes in close places owing to defective local ventilation, due either to the miner responsible having neglected to use the means of ventilation provided, or less commonly to the fact that the means of ventilation provided were inadequate. In every instance in this class carbon monoxide was the predominant cause of death, no doubt with carbon dioxide co-operating in some cases. Nitrous fumes poisoning never occurred under these conditions. It is only caused when the exposure occurs immediately or shortly after blasting, or after the actual burning of explosives.

B. ACCIDENTS DUE TO EXPLOSIVES BEING ACCIDENTALLY SET ON FIRE AND BURNED.

The number of observations which have been made on the composition of the fumes actually evolved when nitro-glycerine explosives are burned in air is not large. Recorded results vary considerably, and the actual result which occurs when accidents from this cause happen underground also probably varies between rather wide limits. Dr. James Moir considers that, if the supply of air locally available in places where explosives are burned is sufficient to allow of vigorous combustion, the amount of carbon monoxide generated may not be greater, and may be less, than when the explosive is detonated. On the other hand, if the supply of air is insufficient, as may happen in a confined space, the amount of carbon monoxide will be increased in direct proportion to the degree of deficiency of air, and that of carbon dioxide correspondingly diminished.

In either case, however, but especially in the latter circumstances, large quantities of nitrous fumes will be evolved, within limits, varying according to the particular conditions present, from 1 to 5 cub. ft. per lb. of explosive burned, blasting gelatine being taken as the type. The latter figure agrees with that of Cullen and Greig.⁶

* I have to thank Mr. R. N. Kotzé, Government mining engineer, for permission to publish these illustrative cases.

Dr. Moir has supplied me with the following figures, which represent the behaviour of blasting gelatine in the several conditions specified in the table:

Table showing Quantity in Cubic Feet of Gases produced by 1 lb. of Blasting Gelatine under Different Circumstances.

Conditions.	CO ₂	N ₂	CO	NO
A. Perfect explosion, without wrapper ...	6.2	2.9	—	—
B. "Practical" explosion, with wrapper ...	5.5	2.9	0.9	?
C. Burned without wrapper in excess of air ...	5.7	2.3	0.7	1.2
D. Burned <i>in vacuo</i> ...	—	—	6.0	5.0

When burning takes place in the dead end of a drive or similar place combustion might be expected to begin as in C, and to finish as in D, according to the available air. The calculations are for pressure and temperature at a depth of 1,500 feet.

These being the determining conditions, one might conclude that nitrous fumes poisoning would be the type of gassing most frequently met with when explosives are set on fire underground, but that carbon monoxide poisoning may also occur. Experience shows that this is actually so, but a rather closer description of what happens is perhaps desirable.

1. When large quantities of explosives, say from 50 to 100 lb., are set on fire, their ignition is frequently followed by their explosion, and this fact introduces an important complication. I have therefore subdivided this group of accidents into two classes, according as explosion did or did not follow ignition. The former class includes one appalling disaster which happened on the Rand some years ago. Happily no accident of similar magnitude has occurred since.

CASE III.—Ignition of 100 lb. of Blasting Gelatine, followed by Explosion: Sixty-one Deaths.

In this case a miner, apparently, so far as the evidence goes, through sheer carelessness, set fire to the explosives in his explosives box at a shaft station. Three other boxes were near by, the four containing perhaps 100 lb. of gelatine, and the whole quantity was involved in the violent explosion which almost immediately followed. The station on which it occurred was completely wrecked, and much damage was caused for a considerable distance up and down the shaft. A large number of natives and some white men were in or near the shaft at the time waiting to ascend to the surface. Three whites and many natives were killed outright or succumbed before the rescue parties could reach them, perhaps an hour later. Many of the bodies were severely burnt; some had sustained other gross physical injuries. In those out of this number who survived the immediate effects of the concussion, shock, and burning caused by the explosion, carbon monoxide poisoning was probably the main cause of rapid death. Other whites and natives died later on from the after effects of fumes, shock, and burning, but, in the absence of fuller information, one cannot push the analysis further.

I have therefore included the whole number under the heading "Indefinite." The eventual toll of deaths was six whites and fifty-five natives. Many members of the rescue parties were temporarily overcome by the fumes, but fortunately none died.

In a smaller accident of the same character perhaps 30 lb. of gelatine was set on fire and exploded, and involved in the explosion a similar quantity of gelignite 20 ft. away. A 6-gallon tin of paraffin was also ignited. Five coolies died later from the burning and battering of the explosion. They were not "gassed," as the fumes did not reach them. But a white miner who encountered the fumes 1,200 ft. away died the same night from acute oedema of the lungs.

2. If we eliminate accidents complicated in this manner, the preponderance of nitrous fumes poisoning in accidents due to burning of explosives becomes at once apparent. Out of fifteen such accidents, carbon monoxide (or mixed) poisoning was the cause of fifteen deaths in one (Case IV), and of one death in a second accident, although in this case other individuals were affected by nitrous fumes. In the other thirteen all the deaths were due to nitrous fumes poisoning.

What appears to happen is this: If the amount of explosives burned is large, and the fumes are met with in great concentration near the site of burning, a rapidly fatal massive poisoning results, which is certainly mixed, but in which carbon monoxide is probably the predominant factor. Or in these circumstances, and in the same acci-

dent, out of a number of persons in close proximity to each other some may be rapidly killed in the way described, while others die later with the typical signs of nitrous fumes poisoning. On the other hand, when the fumes have become dispersed, and therefore less concentrated, nitrous fumes poisoning will practically invariably follow. Each one of these results is well illustrated in Case V, cited below, and the first is clearly shown in Case IV.

The larger accidents of this group quite overshadow those due to poisoning from blasting fumes, since in the former large areas of the mine are quickly flooded with poisonous gases, and many deaths may result. Fortunately the greater number of accidents due to burning explosives are of a less tragic nature. These have occurred from smaller quantities of explosives being accidentally set on fire in the workings through carelessness or misadventure. The insatiable curiosity of natives to find out what really happens when gelatine burns has been the cause of not a few.

In such cases carbon monoxide poisoning may also occasionally result if the fumes are sufficiently concentrated and exposure sufficiently prolonged. Usually, however, when explosives are set on fire there is a hasty stampede to a place of safety. But nevertheless, let me repeat, a very brief exposure to the fumes of burning gelatine or gelignite, even although it be only a stick or half a stick, is quite enough to cause fatal poisoning by nitrous fumes. Nitrous fumes poisoning is therefore the typical and characteristic form of "gassing" under these circumstances. Several deaths have occurred from the inhalation of these fumes in lighting up with the old-fashioned "cheesa" stick, made of strips of blasting gelatine. The use of lighting sticks of this sort has as a consequence been prohibited for some time.

I shall quote three further cases of accidents of this group, each of which illustrates one or other of the points I have mentioned.

CASE IV.—Accidental Ignition of Gelatine Dynamite (15-20 lb.): Carbon Monoxide (or mixed) Poisoning: Fifteen Deaths.

A gang of thirty natives under a white miner were proceeding to their working place in a stope. The natives arrived first; some descended the stope; the others, fourteen in number, remained on the level above, in which, between them and the station, was the miner's explosives box. The miner followed, and had reached his box and passed it, when immediately an alarm was raised. Fifteen, perhaps twenty, pounds of gelatine dynamite contained in the box had become ignited, apparently, so far as the facts are obtainable, through the carelessness of the miner. The boys on the level rushed towards the station, right into the fumes, and all collapsed at once and dropped within a short distance of the box, where their bodies and that of the miner were found. The natives in the stope below the level escaped. Exposure was thus immediate, and apparently death almost equally so.

The blood from three of these cases was examined in the Government Laboratory. In each case it was cherry-red in colour and uncoagulated. It contained a high percentage of carbon monoxide, and the chemical evidence was stated to point to an "oxide of nitro, ei" as a contributory cause. Clearly here the proportion of these gases in the air at the moment, no doubt in conjunction with carbon dioxide also, was high enough to cause immediate unconsciousness and rapid death, and the case may be regarded as one of mixed poisoning, although carbon monoxide was probably the preponderant cause.

CASE V.—Burning of 50 lb. of Blasting Gelatine: Six Deaths from Carbon Monoxide (or mixed) Poisoning; Nineteen from Nitrous Fumes Poisoning; One from Pneumonia.

A white miner, S., was seen at 7.45 a.m., sitting beside his explosives box, which was at the dead end of a short crosscut communicating with a main level (14) and air-way. The explosives box was open, and he had a lamp and candle in dangerous proximity to it. One native witness stated that the candle was actually stuck on the corner of the open box.

A few minutes afterwards a flame was seen in the place. The miner ran out, and having told his own natives who were working near by to turn on the air into their working places, as there was gas about, he went away, and warned no one else. He afterwards denied all knowledge of how his explosives had gone on fire, but was eventually convicted before a magistrate and sharply sentenced.

Several witnesses say that they heard a blast, which may have been due to the explosion of part of the burning gelatine. There was certainly, however, no violent explosion. The fumes poured into the level and were carried by a strong ventilating current up the nearest stope, 70 ft. away, and so to the level above (13). There were natives and a white man (who afterwards died) working in this stope. This man at once ordered his natives out. Six were afterwards found dead or dying in the level above, having been overcome in the attempt to escape. Nineteen other natives died later on in the

mine hospital, and fifteen of these had been working in this same stope. The fumes spread for a considerable distance along Level 13, 600 ft. or 700 ft. in either direction, and ascended to Level 12 through several stopes in which many natives and some white men were working. Many of these were affected.

The medical record of these cases is of great interest. For it I am indebted to Dr. A. H. Watt, of the Simmer and Jack Hospital, who saw and treated them.

The six natives found dead were exposed to the fumes in great concentration, being nearest to the original seat of burning. Death in their case was presumably due to mixed poisoning from carbon monoxide and nitrous fumes.

Fifteen other natives from the same stope and four from other working places died in the mine hospital later with symptoms of nitrous fumes poisoning. Eight of these were dead or moribund on admission. They had not been overcome by the fumes at the time of exposure, and had been withdrawn from the mine in the ordinary way. In fact, during the day and through the evening large numbers of natives were admitted to the mine hospital suffering from respiratory symptoms. Many of these had been working in the stopes between 13 and 12 levels, where the fumes had travelled a greater distance before reaching them. They were recognized as suffering from nitrous fumes poisoning, and in the bad cases free bleeding was carried out, followed by respiratory stimulants. Dr. J. B. Tough informs me that in six natives whom he found comatose with a thin froth issuing continually from their mouths and who were freely bled, the colour of the blood changed during the operation from a dark asphyxial colour to that of oxygenated blood. All six recovered. Excluding those dead or moribund on admission the number treated was sixty-seven. One native died ten days later from pneumonia.

Fourteen white men were also affected by the fumes. What happened to them may be best described in Dr. Watt's own words:

"Thirteen of them" (who, under his orders, came to hospital and were detained there overnight) "had an emetic, and the next day were all out of danger. One man disobeyed orders, and went home without receiving an emetic. He was sent for, but he had gone out for a stroll after having partaken of a hearty luncheon. He was found four hours after the accident, and came to hospital under protest, stating that he felt quite well. In the evening he developed general oedema and congestion of his lungs, and died before morning." This was regrettable, as this particular man had been active in getting the boys out, and had inhaled the gas in so doing.

Unfortunately, the *post-mortem* evidence in this case is incomplete. Not all of the bodies were dissected, as this was unnecessary for the immediate purpose of the district surgeon. Dr. Moiler informs me that those which were examined did not show any signs of carbon monoxide poisoning. The blood was dark and the lungs very oedematous.

Pure carelessness on the part of three white miners was responsible in these two instances, and in the shaft accident already mentioned, for over one hundred deaths. If the regulations regarding the handling of explosives had been observed not one of them would have occurred. The careless miner (we have met with him rather frequently in these records) is a standing danger, not only to himself but to every one near him. Recklessness such as this is not fair play. But these accidents suggest that it might be well to provide all those engaged in the actual handling of explosives with approved (and tested) electric lamps for use in so doing.

I should like to mention, in a word, another occurrence, in which 100 lb. of gelatine was accidentally set on fire by a white learner when capping fuses. He himself and three natives died—the natives certainly from nitrous fumes poisoning. But, although the fumes spread for considerable distances through the mine, no one else died, owing to the prompt and resourceful action of the mine officials. Being immediately warned of what had happened, they at once withdrew all the workmen from the portions of the mine affected to fresh air. This is obviously the only thing to do. Every one should at once get by the nearest way out of the air current bearing the fumes. Rescuers also should be careful to approach places where burning has occurred only from the windward side. The familiar wet handkerchief over the mouth should not be omitted. Several men have saved themselves, when cut off from safety by the fumes, by retreating into a dead end and turning the air on at the face. Sometimes, however, this has not sufficed to protect them from nitrous fumes.

When small quantities of explosives are set on fire, every one should leave the place at once until it has been thoroughly blown out and wetted down. Neglect to do so was the cause of the following accident, the last which I shall quote. In this instance a much smaller quantity of explosive was ignited, and nitrous fumes poisoning followed. Observe once more in this instance the almost

clockwork precision with which this poison does its work. Compare it in this respect with Case I.

CASE VI.—Accidental Ignition of 5 lb. of Gelatine: Nitrous Fumes Poisoning: Four Deaths.

About 1.20 p.m. on a Saturday a miner (G.) accidentally set fire to half a packet (about 5 lb.) of gelatine in a stope. Another miner (H.) and his natives were working at the top of the stope. The fumes ascended the stope to the level above, through part of which men and boys had to pass. G. withdrew his boys and immediately warned H., who left the stope with his natives, and waited with them not far away in the level above for a short time. He then insisted (about 2 p.m.) on returning to charge his holes, although warned not to do so, and took with him a native. He was followed by G. They finished their work and all left the mine together afterwards. H. said he did not feel sick, and both men took the tram home.

Five natives were affected by the fumes. All went to the compound, but about 7 p.m. two became very ill and were taken to the mine hospital. They were spitting blood. One died in a quarter of an hour, the other the following day.

Just at the same time (8 p.m.) the mine medical officer was called to see H., and found him sitting on the side of his bed, with a pulse of 120, expectorating blood-stained sputum. There were signs resembling those of commencing pneumonia at one base. The medical officer made arrangements to send him to hospital the following morning. At 3 a.m. he was dead, thirteen hours after exposure to the fumes.

Two other natives were taken to the hospital at 3 a.m. One died the following day; the other recovered.

The *post-mortem* notes on these four cases were kindly supplied to me by Dr. Stanley Heberden, district surgeon, who certified all as having died from nitrous fumes poisoning. All four reports are couched in almost identical terms. A summary of two will suffice.

Native S. (the boy who died within six hours after exposure). No disease of internal organs. Air passages full of froth; mucous membrane congested; lungs congested and oedematous. Right side of heart engorged with blood. The blood was dark and asphyxial in character. There was no alteration in colour suggesting the presence of carbon monoxide.

R. H. The body of a well-nourished European male. No injuries. The mucous membrane of the air passages is congested and the tubes are full of froth. The lungs are congested and tense with oedema. The right side of the heart is engorged with blood. The blood is dark (asphyxial), and there is no alteration in colour suggesting the presence of carbon monoxide.

MEDICAL TREATMENT.

Regarding the medical treatment of nitrous fumes poisoning there has been a good deal of local experience.

In all cases in the early stage, first produce emesis as soon as possible (apomorphine hypodermically). Follow this by stimulant, ammonia, or (preferably) pituitrin. Then send the case straight to hospital.

Atropine may prove useful in the latent stage.

In the acute stage with developing oedema of the lungs, Macaulay recommends as the first step wet cupping of the chest, back and front. This invariably relieves the symptomatic distress. It should be followed locally by poulticing, or better by jacket mustard-water fomentation, applied very hot and changed every hour.

In all recognized cases of acute oedema free blood-letting should next be performed. This is a most valuable remedial measure. In one of Macaulay's cases, after venesection, the haemorrhagic sputum speedily ceased, and never returned, and the patient made an uninterrupted recovery. Dr. Tough's experience, already quoted, also clearly shows the value of this measure. This has been confirmed by other observers. The condition of the blood may render bleeding difficult, but it should be free (12 to 20 oz.). Venesection should not be delayed until the condition becomes grave. It should be undertaken immediately on the recognition of the nature of the case.

Follow venesection by saline infusion, and repeat this if necessary.

Administer oxygen intermittently to relieve and tide over the asphyxial condition.

Give ammonia in repeated doses.

Injections of pituitrin (1 c.cm.), repeated every four hours, should be tried. I have found this drug, used in this way, of great service in the treatment of acute pneumonia.

These are the lines of treatment which have been followed locally, and in a considerable number of cases with marked success, although when the condition of acute oedema is well established probably a majority of cases will die in spite of treatment.

I had written the above notes before I had an opportunity of seeing the very valuable report by Lieutenants Elliot Black,

Glenny, and McNee, R.A.M.C., on Cases of Poisoning by Noxious Gases used by the Enemy.⁷

NOTE ON CASES OF PHLEBOTOMUS FEVER AT AN ISLAND IN THE EASTERN MEDITERRANEAN.

By J. T. D. S. HIGGINS, M.B., B.A.,
SURGEON, R.N.

EIGHT cases of phlebotomus fever occurred amongst the officers and men attached to the garrison under my charge. These were due to infection by *Phlebotomus papatasi*. Seven cases occurred between July 21st and August 1st, 1915, and one other case on August 9th.

Six of these cases occurred in one locality and in one house. The patients were either mess-servants, sentries, or officers (1) who were on duty at and slept in this house. One case was an officer's servant (Private R.M.L.I.). He came in from another camp, and slept one night at the house. On the morning of the fourth day afterwards he became ill with the fever. All the other patients had numerous marks of bites. They resembled mosquito bites; but the sandfly bites silently; it does not give warning of its presence by any peculiar musical note, as does the mosquito. A very faint note may sometimes be heard if the fly passes close to one's ear. The sudden sharp sting, when the phlebotomus bites, is sufficient to wake one from sound sleep.

After the first case, on account of the type, sandfly infection was suspected; the suspicion became greater when the localized incidence at the house became marked. A search was made for phlebotomi in the house, *Culex* larvae (? dengue) being searched for at the same time in the wells, etc., as the marks on patients' wrists and ankles closely resembled mosquito bites. No *Culex* larvae were found, but phlebotomi were found in the house, and later inside the mosquito net of an officer, who had been severely bitten and developed the fever. These were caught and proved to be *Phlebotomus papatasi*. Although specimens had been seen at the Royal Naval College, Greenwich, during the tropical course, after entry, I was not certain that this was the genuine sandfly, but the diagnosis was confirmed by Colonel Garnier, R.A.M.C., Egyptian Medical Service, and they were later examined in company with Dr. A. De Lisle, attached to the French Army Medical Service.

The following prophylactic measures were taken:

1. The sleeping place of mess-servants and sentries was changed from the hall on the ground floor to the lobby on the next floor higher up.

2. A space of ground alongside the house, but not part of the premises, contained old rubble, refuse, and fallen masonry, and was thought to be the probable breeding place and habitat of the fly. This was cleared and covered with lime; quicklime was applied for in order to spray or wash down all these old walls and crevices, but was not immediately available.

After these measures were taken no fresh case occurred, but this was probably in part due to the fact that a slight change in the weather followed, and the temperature dropped below 70° in the evenings, which is unfavourable to the continued presence of phlebotomi. The weather during June and early July was probably too hot and dry for the larvae to hatch out.

As was gathered subsequently from articles published in the *BRITISH MEDICAL JOURNAL*, and seen by me in September, prophylactic measure No. 1 above was probably more effective in the circumstances than was hoped for at the time. In the place where the men previously slept they were exposed to the flies from the

rubble, etc., which was only a few yards away across a narrow by-way, and level with the open windows of the hall, so that the flies entered each evening, probably attracted first by the light inside. As the phlebotomus does not tend to ascend much in flight these flies probably did not reach the second lobby, where the men afterwards slept. Although they remained in some of the rooms during the day this lobby was too bright to suit them, and there was always a free draught there.

The case which occurred on August 9th, 1915, was that of a ship's steward (pensioner, aged 43). This case occurred at another building, an old castle. His office and store were in a part of the castle suitable for the fly, that is, inside one of the old stone turrets. This building was not used by the men.

The flies were of a dull pale yellow or sand colour. Two dots of black pigment at the eyes were conspicuous when the fly was caught. The body was curved on itself in hump-backed fashion. The wings were long and narrow, and with a magnifying glass were seen to have long fine hairs along their edges. The wings (at rest) were always carried pointed backwards, upwards, and outwards from the body, diverging from each other. When an attempt was made to capture a fly it did not fly forward, but eluded capture by seeming to jump off at a right angle, alighting again about six or eight inches away in a straight line to right or left.

GENERAL DESCRIPTION OF THE CASES.

Incubation.

From the case of the private (R.M.L.I.), and from consideration of the time of onset after first noticing the bites, this appears to have been about three days.

Symptoms.

The onset is sudden; the patient's face is flushed and eyes puffy and injected as if he had been drinking heavily. He complains of dizziness, severe headache, and pains, generally in the back and region of the hip-joints. He is "tired" and feels very ill. In two of the cases there was nausea and slight vomiting at the onset. The temperature was generally about 101° at the onset, but usually reached 103° or more within ten hours. On the second day it was usually about 101°. In three of the cases it eased to normal on the evening of the second day. In the others it did not reach normal until the evening of the third day or later. After becoming normal, in several cases a rise next day to 99° or 99.4° was noted, the temperature afterwards steadying at normal.

During the night of the first day and subsequently, pain in the back, sacral region, and joints was marked, and also pain across the eyes; the eyeballs are rather tender to pressure. The patient slept little and did not sweat. By the second day the tongue was covered with a white fur, except at the tip, and the patient had no appetite. One patient had slight diarrhoea, but the others were constipated. The pulse-rate was never more than 80 in any of the cases, even when fever was high. In one case there was slight sore throat, and in another slight stupor and delirium on the third night.

After Effects.

A general feeling of fatigue and lack of energy, mental and bodily, lasted for some time. All cases showed this to some extent, but in three it was much less than in the others; these three cases were "two-day" cases. The others remained unfit for duty for a week or longer. The pains and feeling of stiffness sometimes remained. Although the patients said they felt well, they walked about shakily, and as if shrunken inside their uniforms. Their voices were noticed to be weak and rather higher pitched than normally.

Treatment.

During the attack acetyl-salicylic acid was freely given. Quinine was given to the first two cases, but discontinued when it was seen that they were not due to malaria and that quinine did not appear very effective. During the after-period mist. Fowleri was given for about a week.

In his article on phlebotomus fever at Peshawar, published in the *BRITISH MEDICAL JOURNAL* of July 31st, 1915, Captain Houston, M.B., R.A.M.C., remarks on the tendency of the infection to "cling more particularly to certain bungalows." It is interesting to note that the infection met with above was almost exclusively experienced at one particular house. Also, the detailed corre-

spondence of the symptoms noted above, with accounts published in the *BRITISH MEDICAL JOURNAL* for Indian phlebotomus, is at once striking and interesting for one without previous experience of this widely-distributed infection.

THE TEMPERATURE NECESSARY FOR THE DESTRUCTION OF LICE AND THEIR EGGS.

By A. W. BACOT,

ENTOMOLOGIST TO THE LISTER INSTITUTE.

THE points concerning temperature dealt with by Dr. Kinloch in his valuable contribution on lice, published in your issue of June 19th, 1915, were so at variance with my experience regarding the heat necessary to kill other insects that I felt impelled to test the matter for myself.

Bugs (*Cimex lectularius*) have been shown by Blacklock (1912) to die at 45° C. (113° F.); subsequent experiments by myself (1914) confirm this, and also show that fleas (*Xenopsylla cheopis*) and cockroaches (*Periplaneta americana*) are destroyed at this temperature, or a few degrees higher. Reports of experiments with mosquitos (*Stegomyia fasciata*), performed under the auspices of the Yellow Fever Commission (West Africa), now in course of publication, show that about the same degree of heat is also critical for these insects.

Living specimens of lice—*Pediculus humanis (vestimentis)*—were obtained from two separate sources and treated as a single stock, from which the active insects and nits required for the following experiments were drawn. The breeding method adopted was to line an entomological glass-bottomed box with a slip of dark-coloured cloth and cover the top with chiffon,* through which the insects were fed. This box was nested in one of a larger size for safety and carried in a pocket where the insects had the advantage of the natural heat and humidity of the body.

The method used in the tests was as follows: Pieces of cloth with eggs and active lice on them, or with one or the other only, were taken from the stock box and divided, one portion being kept as a control, the other used for the test. If active lice were present, the piece of cloth was placed in a similar box, covered with chiffon, but if the nits only were tested the cover was not used.

It was found that both the eggs and lice (in their second instar) survived a thirty minutes' trial in an incubator (dry air) at 49° C. (120.2° F.), the lice being apparently unaffected, as they subsequently completed their development. Living lice, however, were killed by thirty minutes' submersion in water at 50.2° C. (122.3° F.); at the same temperature in dry air they were paralysed and rendered incapable of other movements than a feeble motion of the legs; 28 out of 32 specimens in all stages of growth died within a few hours, but 4 (two in the second and two in the third instars) survived.

Another trial was carried out at 54° C. (129.2° F.). Thirty-five minutes after the lice were placed in the incubator they were all dead, and, up to the time of writing—over three weeks after the test—no young have emerged from the eggs submitted to this temperature, though the control box is swarming with lice in all stages of growth.

Eggs on pieces of cloth were dipped into water boiling at 98.4° C. (209.1° F.) for one minute and a half-minute respectively, and, as was to be expected, they turned opaque white, presumably owing to the coagulation of the albumin. They were, however, kept in entomological boxes and carried in the same pocket as the control eggs; these latter duly hatched, but the tested eggs shrivelled up after drying.

A further test was carried out in a water bath to ensure greater accuracy. One batch of eggs was placed in tap water in a tube, stoppered with cotton-wool, and another portion of the same batch of eggs was placed dry in a similar tube; both the tubes were submerged to within an inch of the rim in the water bath, the registered temperature of which was 55° C. (131° F.). After thirty minutes the eggs were removed and placed in separate boxes, the

control portion being placed in a third. All three boxes were kept together in the same pocket. Up to the time of writing (sixteen days after the trial) no eggs have hatched in either of the test boxes, while many active lice in various stages of growth are present in the control box.

While it is, of course, possible that eggs having a long hatching period may survive a temperature which kills those which develop more rapidly, it is so improbable that I have no hesitation in concluding that dry heat or submersion in water at 55° C. (131° F.) kills both active lice and their eggs. It follows as a consequence that considerably lower temperatures than those usually employed may be used to destroy these vermin. For the thorough sterilization of infested garments the question of penetration is all-important. It is probable that considerable economy in fuel might be effected by allowing a longer exposure at a lower temperature, while it should be practicable to use quite lightly built chambers or temporarily adapted rooms to obtain dry air temperatures of, say, 60° C. (140° F.)

MEDICAL, SURGICAL, OBSTETRICAL.

CREOSOTE IN RHEUMATISM AND GOUT.

OWING to the great rise in price of acetyl salicylic acid and sodium salicylate, I made a trial as a substitute of creosote in ½-minim doses given in the form of a mixture, as follows: Magnesium carbonate (heavy), 3j; creosote, viij min.; peppermint water to viij fl. oz. The dose for an adult is one tablespoonful every four hours, with an equal quantity of water.

If pain is severe, the addition of from five to seven minims of liquid extract of opium to each dose is valuable; and when the pain is due to acute gout, the further addition of from seven to ten grains of potassium bicarbonate is also good. In cases of arthritis, associated with great loss of lime salts, prepared chalk (ten grains), or aromatic chalk powder (ten to fifteen grains), may be added with good results.

I have found that cases of acute gout treated on these lines, combined with suitable local treatment, are rapidly relieved, the patient being able to return to his work in less time than before, whilst the interval between the attacks seems to be lengthened.

In cases of catarrh and influenza, with feverishness, it is a good plan sometimes to substitute for the peppermint water solution of acetanilide (2½ grains to the ounce), made previously with boiling water and cooled—the flavouring being made by essence of peppermint.

Cases of lumbago, sciatica, fibrositis, neuritis and arthritis of various types, seem to do quite as well with the creosote treatment as with the salicylic, and one decided advantage is the absence of severe gastric disturbance associated with the use of acetyl salicylic acid in some cases, as shown by anorexia and nausea. In fact, the creosote mixture (modified if necessary to suit individual cases) is of use in gastric and intestinal disorders, and replaces bismuth salicylate very well in some cases.

For patients unable to tolerate the smell or flavour of creosote, as well as for other cases, the substitution of sodium sulpho-carbolate gives good result.

I send these suggestions in the hope that they may help to cut down expenses in panel and dispensing practice, and to obviate the difficulty in obtaining a sufficient supply of the salicylic compounds.

DYSTOCIA DUE TO CONSTRICTED OS.

HEERMAN, in his valuable work on difficult labour, refers to dystocia due to the very rare condition of smallness of the os externum, and the following case is recorded on this account:

A young woman had suffered from procidentia uteri; the uterus had been ventro-fixed by operation, but the procidentia thereafter completely recurred. She became

* This method is fully explained in A Study of the Bionomics of the Common Rat-flea and other Species associated with Human Habitations, etc., *Journal of Hygiene*, Plague Supplement III, January 14th, 1914, p. 465.

pregnant for the first time, and on a Sunday began to have labour pains. On the following Tuesday the maternity nurse, having been sent for, called us in, because she could not find the os uteri, although the globose head appeared to be low in the pelvis.

By digital examination we found that the cervix was completely relaxed, but the os externum could not be felt; inspection through a good speculum, after some considerable search, revealed a very small opening, which would just admit a director. It was decided to administer a suppository containing $\frac{1}{4}$ grain of morphine, and await events.

After the expiration of twenty-four hours the pains were strong and regular, and the pulse was increasing in frequency; the speculum enabled a three-pronged cervical dilator to be inserted into the os; the blades were separated to their limit (1 in.), when amniotic fluid, mixed with meconium, escaped in quantity.

The os was now, with the greatest possible ease, dilated by a sweeping movement of the finger, and gave way to the full extent in a very few minutes. A dead child was naturally born, the second stage of labour occupying about half an hour.

The interesting points about the case appear to us to be: (1) In view of the unknown etiology of this condition, the question as to whether the procidentia may have unnerved the dilator mechanism of the external os, this patient having habitually worn, as it were, the cervix uteri outside her body; (2) the rarity of the condition; (3) the remarkable way in which the os adopted its normal behaviour and gave way readily when, so to speak, it was frightened by a dilator.

IMPROVED TECHNIQUE FOR INTRAVENOUS INJECTIONS AND REMOVAL OF BLOOD FROM VEINS.

MAY I say a word in confirmation of Dr. Alfred Codd's suggestion (JOURNAL, December 11th, 1915, p. 861) of the sphygmomanometer as an apparatus for blocking the venous flow in the upper limb when it is desired either to introduce remedies into the blood stream or to withdraw blood from the veins? I have used this method for some time and can fully endorse all that Dr. Codd says of its value. Personally, I find an instrument with an aneroid index more convenient than the more bulky mercurial register, but really neither the one nor the other is necessary if a clip is fixed on the india-rubber tubing attached to the ball pump on the side remote from the index; the amount of pressure needed can be readily regulated by the finger placed over the radial artery. Either with or without this modification it is perfectly easy to give an intravenous injection without any assistance other than that which the patient can afford, and this is one of the special merits of the method. All that is necessary is to place between the patient's thumb and index finger of the limb which is not being operated on the clip in the one case, or the junction of the india-rubber tube and the ball-pump in the other, and to instruct him to make the required manœuvre at the word of command. The release of the pressure is instantaneous—even more rapid than from a turn of the escape cock—and this without the slightest risk of dislocating the point of the needle from the interior of the vein.

As a practical point I would add that the armlet prior to inflation should not grip the arm too closely; unless this is remembered there may be, even after the airbag has been emptied, sufficient pressure to cause blood to escape from the punctured vein and so to produce an unnecessary haematoma.

London, W.

C. O. HAWTHORNE.

THE volume of *Studies from the Department of Pathology of the College of Physicians and Surgeons, Columbia University*, consists of reprints of monographs and reports representing the results of the work done in that department during the collegiate year 1913-14. The cost of reprinting and issuing the studies is defrayed by a special grant from the university itself, and no longer, as before, by an association of its alumni. The collection includes some valuable scientific reports.

Rebueluz.

TWO WAR BOOKS.

MR. J. M. ROBERTSON, M.P., in his *War and Civilization*,¹ has reverted to the fashion of the polemical letter. It proves most excellently adapted to his purpose and to his style, for, though he is widely read in German, he is too deeply steeped in Elizabethan English to be anything but direct when he wishes, and in this letter he is very direct.

The letter is addressed to Dr. Gustaf F. Steffen, Professor of Economics and Sociology, Stockholm, who three years ago was professor of the same subjects at Gothenberg. Professor Steffen, it is stated, published a book in Swedish early in 1915, which has been translated into German with the title *Krieg und Kultur*. Professor Steffen's main proposition seems to be that if of two combatant nations one can, in his opinion, lay claim to higher intellectual qualities and a more zealous cult of the State than have been developed by the other, it is justified in any way it wages, on any pretext, with that antagonist. Mr. Robertson is puzzled, as well he may be, that a work of a professed student and teacher of social science should take as an absolute premiss the inevitableness of a German effort to destroy the British Empire, while at the same time laboriously criticizing British writers who take a hostile view of Germany's action in precipitating the war. Professor Steffen's thesis seems to be somewhat as follows: Germany desires to expand at the expense of other nations, and such a right vests in those willing to exercise it. Germany will be able to exercise it when she crushes Britain and destroys its command of the seas. The rights of other States do not count. Not being able to make a successful aggression they have no right to resist, and those who cannot resist aggression have no rights at all. Germany is a great and gifted and noble-hearted nation, which has produced admirable music. Her militarism is necessary to her. What Britons ought to do is resign themselves to her inevitable supremacy.

If this be so, the attitude of the German is due to a mixture of pride and envy, and, says Mr. Robertson, "we are no more surprised at his new ethical positions than we were at those of the company of *Gelehrten* who defended the infernal wrecking of Belgium by asserting the superiority of German Kultur. We are, in fact, now incapable of being surprised at any ethical developments that may take place in a country in which the gospel of war for war's sake has become predominant. That seems to be really the fundamental issue." Mr. Robertson then proceeds to examine the allegations as to the ennobling effects of war on character, but we have said enough already to show the character of his book, and need only perhaps deal with one other matter. To many readers of our profession the most interesting part of his letter will be, we suspect, the section on the pseudo-science of national psychology, and those following in which the subject is developed. *Völker-psychologie* is the so-called science which labels the French as frivolous, the German as solid, the Russian as dreamy, the English as slow-witted, the Irish as quick-witted, the Scot as cautious, and so on. No one with any adequate knowledge of men, or even with a sense of humour, would take labels of this sort seriously, but the Germans took *Völker-psychologie* very seriously; it ministered to the frame of mind which led them to believe that the German type of civilization, the German way of thinking, power of organization, and so on, were superior to those of all other nations, and that therefore they were justified in provoking the war and the atrocities committed by themselves in Belgium, and by their allies, the Turks, in Armenia. Since, as the history of Germany itself shows, a race can change its psychology from generation to generation, nothing, scientifically speaking, is left of *Völker-psychologie* but the conception of political aggregates of human beings of a given grade of culture, swayed for the time by prevalent teachings and induced states of mind. Mr. Robertson sums up his thesis in the following sentence, with which his book concludes: "The psychology of your friends is the psychology of the braggart. The science of war they

¹ *War and Civilization: An Open Letter to a Swedish Professor*, By the Right Hon. J. M. Robertson, M.P. London: George Allen and Unwin. 1916. (Cr. 8vo, pp. 160. 2s. 6d. net.)

mastered like the other physical sciences; and they took for granted that their mere barbaric instinct, their race-pride, and their appetite to power yielded them a science of man, a *Völker-psychologie*, in which their ascendancy was deducible even as might be the operation of an explosive shell in physics. That is to say, in the most essential knowledge of all, in comprehension of the vast process of international action and reaction, of the way of working of the souls of nations and of free men, they are the most profoundly unscientific of all the civilized peoples, and by consequence they are the most barbarous. That is my thesis."

We trust that we may not, by any such defect in this notice, have given the impression that Mr. Robertson's letter is in the least dull; there is not a dull line in it, and, apart from the brilliancy of the whole argument, it contains some striking quotations from German documents, including extracts from the diary of Private Becker (in civil life professor of Latin at the Bonn Gymnasium), which contains part of the story of the inimitable Lieutenant Reinicke and how he got the Iron Cross.

A book of a very different kind is *German Culture*,² edited by the Professor of Divinity in the University of Edinburgh, and published last year. It contains a series of essays, written for the most part by Scottish professors, in which an attempt is made to appraise the value of the contribution of the Germans to knowledge, literature, art, and life. At the outset the editor is in trouble to find an English equivalent for "Kultur," and defines it as civilization viewed on its higher side, but we would add, with a special limitation to the German variety, based on the ideas of State organization in civil life and terrorism in war. The longest essay, and that which bears the title, "What science owes to German investigators," is by Professor Arthur Thomson of Aberdeen, and though it could not have been in better hands the result is not satisfying. Professor Thomson does not really grapple with the German thesis, which is, not that science owes much to German investigators, but that Germany is supreme in science, as in other departments of human activity. Professor Thomson does not subscribe to this claim to supremacy, but sets himself to prove that "it is as inaccurate as it is ungrateful to belittle the debt of science to German investigators." He gives lists of the men most distinguished in the various sciences in parallel columns, Britain, France, Germany, other countries—we should like to quarrel with him for arranging them in alphabetical order, which means nothing, instead of chronologically, which would have meant a good deal. Of the names of living men in the German column most, if not all, were among the 93 who signed the deplorable declaration by German professors and men of science. The arrogance and narrowness of mind displayed in the manifesto produced a reaction in this and other countries from an attitude of undue adulation and imitation to one severely critical. We believe the reaction to be healthy and for the good of all the nations, including the German. Germany claimed supremacy in science as it claimed hegemony in Europe and, indeed, throughout the world, including the western hemisphere. The claim to hegemony was in fact founded on the alleged supremacy. The fact is that, as Professor Thomson in the end seems to have recognized, he set himself an impossible task. He has not been content to fulfil the promise of the title of the volume by giving an account of the contributions of the Germans to scientific knowledge, but has attempted to appraise the value of German contributions, not to the details but to the inspirations of science, as compared with those of other nations. Science is more truly cosmopolitan than any other sphere of intellectual activity; it is, in fact, universal. A mathematical analysis, an observation of a physical phenomenon, or a chemical equation, can have no national or racial colour. All three will hold good not only all over the world, but throughout the whole solar system and beyond. They can only acquire a national colour when it comes to their interpretation, to their manipulation to establish or refute a hypothesis. Moreover, as Professor Thomson recognizes near the beginning of his

essay, nationality is an insufficient basis for the scientific analysis of intellectual tendencies and capabilities. The really interesting criterion which would satisfy scientific demands would be race, not nationality. Now, the nations of Europe and North America are made up of a mixture of races, and, as he admits, "perhaps the greatest difficulty is in regard to the Jewish element in the various nations, for the Jews have been extraordinarily inventive and independent, especially in certain departments, such as physiology and pathology. As we have not been able to discriminate the Jewish strain, we have probably given the various nationalities considerably more than they deserve." The general effect of what Professor Thomson has to say is that the Germans are diligent workers, have produced many eminent teachers, some of whom have founded important and prolific schools of research, and a few men who have really made new roads into regions previously closed. He does not say, as we think a strictly impartial historian might have said, that organized research in Germany has also been a sower of tares, and that far too much of the energy of research workers in other countries has had to be given to clearing away the weeds.

Though the writers of nearly all the essays are Scotsmen, the shortest, and perhaps the best, is by a Yorkshireman who has returned to his own county to serve the University of Leeds as vice-chancellor. Dr. Sadler sees very clearly both the strength and weakness of German education. Its strength lies in its extraordinary precision of aim, its high standards of intellectual attainment, its liberal encouragement of organized scientific research, and its wide diffusion and convenience of access. But it has been so framed as to place a weapon in the hands of the dominant power of the State; "the glorification of the State has included the sacrifice of the individual, and that has been conducted ruthlessly in Germany"; and, again, "it has made the minds of individuals too susceptible to current intellectual fashions and has left them deficient in the power of independent criticism and of resistance to governmental control." Is it too much to hope that one of the lessons we shall learn from the hideous misconduct of the Germans will be to avoid the downward path along which some who have been inoculated with the German virus would drive education and the professions in this country?

PRACTITIONERS' ENCYCLOPAEDIAS.

*The Practitioner's Encyclopaedia of Medical Treatment*³ is an endeavour to produce a single comprehensive volume on the subject, written by men of wide understanding and experience. It consists of three parts. The first, over 500 pages in length, deals with the methods of treatment to be adopted in the various disorders with which the practitioner is likely to meet, considered under one hundred and twenty headings and more. The second part is devoted to the agents employed in medical treatment, and extends to 270 pages. Here the reader finds compact and up-to-date accounts of the pharmacological actions of the drugs, preparations, and drug-foods that the practitioner may employ with advantage. The third part of the volume is the excellent index, 100 pages in length, in which will be found references to the pages where special information may be found on diseases he has to treat, and drugs or methods of treatment he desires to employ. The introduction is a brilliant piece of writing from the pen of Sir CLIFFORD ALLBUTT, who gives a most engaging survey of the new from the standpoint of the old in the treatment of disease. The editors are to be congratulated upon the excellence of the staff they have collected for the composition of their *Encyclopaedia*. The individual articles of which it is composed appear to reach and to maintain a high level of practical excellence, and to contain just the information for which the medical practitioner is ever on the look-out. We cannot do more than recommend the book most highly, and congratulate the editors, Dr. LANGDON BROWN and Mr. KEOGH MURPHY, upon the success of their venture.

² *German Culture. The Contribution of the Germans to Knowledge, Literature, Art, and Life.* Edited by the Rev. Professor W. P. Paterson. London: T. C. and E. C. Jack. (Cr. 8vo, pp. 384. 2s. 6d. net.)

³ *The Practitioner's Encyclopaedia of Medical Treatment.* Edited by W. Langdon Brown, M.D., F.R.C.P., and J. Keogh Murphy, M.C., F.R.C.S. With an introduction by Sir T. Clifford Allbutt, K.C.B., M.D., F.R.S. Part I: Methods of Treatment. Part II: Agents in Treatment. London: H. Frowde, and Hodder and Stoughton, 1915. (Sup. roy. 8vo, pp. 897. 35s. net.)

The appearance of this volume affords an opportunity, which we gladly take, of noticing the appearance of the second edition of *The Practitioner's Encyclopaedia of Medicine and Surgery*.⁴ This came out within a year of the issue of the first edition, a fact that may be taken to show that the book supplied a definite want. It is not too much to say that it is a work reflecting the highest credit on its editor, Mr. KEOGH MURPHY, and his many scores of contributors. Here the practitioner will find covered the whole field of medical and surgical practice in all its branches, and covered well. Medicine, surgery, anaesthetics, obstetrics, gynaecology, diseases of the special organs of sense, diseases of the skin, and special forms of treatment, all receive exhaustive consideration in turn. The articles are full of information useful to the general practitioner; where necessary, illustrations have been added to improve the clearness of the text. The book is one that should be in the hands of every practitioner of medicine, unless, indeed, he chances to own a copy of the first edition.

PRIMARY TUBERCULOSIS OF THE LUNG IN CHILDREN.

THERE has always been some dispute as to the primary focus of the tuberculosis in children with tuberculosis of the lung. According to one view the focus in the lung is the primary focus, the tuberculosis of the neighbouring peribronchial lymphatic glands being secondary. The other view maintains that the infecting tubercle bacilli lodge first, so far as the lungs are concerned, in the lymphatic glands, spreading thence in a retrograde manner into the lung and setting up a pulmonary tuberculosis that is secondary. Much work has been done on the Continent to settle this point. A book was written about it by Dr. A. GHON of Prague in 1912, and this has now been translated into English by Dr. BARTY KING.⁵ Here we have a full account of the *post-mortem* examination of the lungs and bronchial glands in 184 tuberculous Viennese infants and children. In 170 of these there was a primary focus in the lung, as Dr. Ghon's analysis shows; in 14 no focus could be detected in the lung. The final conclusion reached is that the lung was the primary focus of infection in 162 cases, and in 15 more another organ besides the lung came under the category of channel of infection; in 3 the small intestine, in 1 the right tonsil, in 1 apparently the skin was the primary focus, and in only 2 cases could no channel of infection be recognized. Good reasons exist for believing that in the young the lungs are infected with tuberculosis by inhalation, and not by the blood stream or lymphatic channels. In childhood, therefore—at any rate, so far as the city of Vienna is concerned—a primary infection of the lungs represents the usual form of tuberculous infection. The translator has done his work adequately, although such diagnoses as "meningitis Weichselbaum" (p. 52) and "pseudo-membranous angina" (p. 17) smack more of the German than the British tongue. The book should be read by pathologists and those who are especially interested in tuberculosis.

NOTES ON BOOKS.

*Whitaker's Almanack*⁶ for 1916, the forty-eighth annual volume, appears with an apology from the editor for its later publication, the delay being due, it is stated, largely to causes arising out of the war, including difficulties in the various departments of production. The general arrangement and scope of the volume has not been changed, but the navy and army lists have been curtailed owing to the scantiness of official information. On the other hand, there are two articles on the war—the one a diary bringing matters down to the end of October, 1915, and the other a consecutive history of the military and naval operations. There are several articles on national finance, including particulars of the war budget and taxes, and a table showing the amount of tax payable on incomes of

various amounts. There is a useful note on trading with the enemy, and the duties of the Public Trustee in respect of enemy property. There is also a short article on the national dye scheme which, if successful, may eventually have considerable influence on the price of synthetic drugs. Altogether the volume for this year has been brought well up to date, and is a no less indispensable desk companion than the previous issues.

The ninth edition of Drs. WARWICK and TUNSTALL's *First Aid to the Injured and Sick*,⁷ an advanced ambulance handbook, comes two years after the eighth edition. It is accompanied by a set of questions whereby the success with which the learner has perused it can be tested. The book is one of proved utility and excellence, written in concise style, full of useful information. The authors might with advantage recast the account of "Shock by Electricity," given on p. 163, emphasizing the importance of immediate recourse to artificial respiration in such cases, and the necessity for continuing therewith until either the patient has recovered or it is certain that death has taken place.

The thirteenth volume of the *Laboratory Reports of the Edinburgh Royal College of Physicians*,⁸ edited by Drs. GRAHAM BROWN and JAMES RITCHIE, contains thirty-two papers by eighteen authors. They deal with subjects in protozoology, anatomy, biological chemistry, pathology, and bacteriology, and include four articles that first appeared in the *BRITISH MEDICAL JOURNAL* during 1913 and 1914. Nothing could furnish more satisfactory evidence of the vitality of the study of medical science in Edinburgh than is afforded by the publication of this interesting and well-filled volume. Many of the articles are of the first importance, from a practical as well as a scientific point of view, and none fall below a high level of excellence. It is gratifying to find that even in the present time of stress the study of pure science is not being neglected.

Volume xlii of *St. Thomas's Hospital Reports*⁹ deals with the cases admitted during the year 1913. Its contents are divided into eleven sections, and these deal in a summary or statistical manner with the activities of the various hospital departments among both out-patients and in-patients. These reports should be of particular interest to St. Thomas's men, and are of value as showing the proportions in which the various surgical, medical, and gynaecological disorders come up for treatment in a great London hospital at the present time.

It is to be regretted, perhaps, that statistics do not always command the respect that is their due. The man in the street is apt to connect them in his mind with the paradox, "lies, d—d lies, and statistics"; the French have defined them as *le mensonge en chiffres*. As a corrective to such injustices as these may be mentioned a recent monograph on *Mortality Laws and Statistics*,¹⁰ in which the mathematical treatment of the subject is thoroughly expounded. To any one familiar with the employment of logarithms and disintegration, functions and summation, the volume should be of no little service; to less accomplished mathematicians it will remain a sealed book.

In his brief account of *Catalysis and its Industrial Applications*,¹¹ reprinted from the *Chemical World*, Mr. JOBLING gives an account of the chief of the many uses to which catalysts are put in chemical industry. The book is highly interesting reading, but demands a certain amount of chemical knowledge for its due appreciation. The notion of catalysis was introduced into chemistry by Berzelius as long ago as 1835; an exact definition of what is meant

⁴ *The Practitioner's Encyclopaedia of Medicine and Surgery in all their Branches*. Edited by J. Keogh Murphy, M.C. Cantab., F.R.C.S. Second Edition. London: H. Frowde, and Hodder and Stoughton. 1913. (Sup. roy. 8vo, pp. 1469. 35s. net.)

⁵ *The Primary Lung Focus of Tuberculosis in Children*. By Dr. A. Ghon. English authorized translation by D. Barty King, M.A., M.D. Edin., M.R.C.P. Lond. and Edin. London: J. and A. Churchill. 1916. (Roy. 8vo, pp. 196; 2 plates, 72 figures. 10s. 6d. net.)

¹⁰ *Mortality Laws and Statistics*. By R. Henderson. No. 15. Mathematical Monographs, edited by M. Merriman and R. S. Woodward. First edition. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1915. (Med. 8vo, pp. 114. 5s. 6d. net.)

¹¹ *Catalysis and its Industrial Application*. By E. Jobling, A.R.C.Sc., B.Sc., F.C.S. Textbooks of Chemical Research and Engineering. London: J. and A. Churchill. 1916. (Cr. 8vo, pp. 128; 11 figures. 2s. 6d. net.)

by the term is no longer possible, owing to the multiplicity and variety of the catalytic reactions known and employed nowadays. A well-known definition of a catalytic agent or catalyst states that it is "a material which affects the velocity of a chemical reaction without appearing in the final products." The drying of oil paints may be quoted as a catalytic process familiar to all. Mr. Jobling writes clearly so far as the obscurity of his subject admits, and covers a great deal of ground in his excellent little book.

It would not be easy to find a more striking instance of the power of science to unravel the complexities and to illuminate the obscurities of Nature than is supplied by Mr. COULTER's account of our present knowledge of *The Evolution of Sex in Plants*.¹² The subject abounds with traps for the unwary, and, until quite recently, botanists, misled by the superficial resemblance of the processes of reproduction among plants and animals, have been lending authority to popular misinterpretations which are now being abandoned. The key of the situation is to be found in the proclivity of plant life to an alternation of sexual and asexual generations, so that there are two kinds of individuals in a life cycle—the sporophyte producing spores but not gametes, and the gametophyte producing gametes but not spores. The gametophyte or sexual plant, which began in the thallophytes near the foot of the evolutionary ladder, has in the seed plants disappeared from ordinary observation, and become a dependent internal parasite of the asexual individual or sporophyte. The evolution of the sporophyte is the reverse. It appears among the cryophytes as an inconspicuous dependent upon the gametophyte; among the seed plants it is the only individual seen. Hence the stamens and pistils of a flower contain "the spores that in germination produce male and female gametophytes." They themselves are products of the asexual spore-producing plant which has monopolized the vegetative functions of the species. Low down in the scale, among the algae, we find individuals giving off cells which on division form ciliated spores of various sizes; the largest germinate independently and form new individuals, while the smallest usually, though not invariably, pair before germination. Here, then, we have both spores and gametes produced side by side from the same individual, indistinguishable except by size and behaviour, and the history of reproduction in plants is largely that of the gradual working out of a blend of the two modes of reproduction. Mr. Coulter tells his story in a fashion which holds the reader's interest. On the part played by nutrition, environment, and metabolism in the sexual sphere he has views of his own well worthy of attention.

¹² *The Evolution of Sex in Plants*. By J. M. Coulter, Head of the Department of Botany, the University of Chicago. The University of Chicago Science Series. Chicago: The University of Chicago Press; Cambridge: The University Press. 1915. (Cr. 8vo, pp. 140; 46 figures. 4s. net.)

HYPOCHLOROUS ACID IN SURGERY.

At the request of the Medical Research Committee an investigation on antiseptics was undertaken in the department of pathology of the University of Edinburgh in January, 1915. Comparison of the different types of antiseptics led to a general conclusion embodied in the paper entitled "Experimental observations on the antiseptic action of hypochlorous acid and its application to wound treatment," published in this JOURNAL, by Drs. Lorrain Smith, Murray Drennan, Rettie, and Campbell, on July 24th, 1915, p. 129. The name "eupad" was given to the powder and that of "eusol" to the solution. At that date a considerable amount of surgical experience on the subject had already accumulated, but at a meeting summoned by the president of the Royal College of Surgeons of Edinburgh on August 10th, it was resolved to institute a more extended clinical investigation by the combined action of a number of surgeons in Edinburgh. A report by this committee has now been presented to the Medical Research Committee, and will be published, we are informed, in full in the *Journal of the Royal Army Medical Corps*.

The report points out that solutions of alkaline hypochlorites have long been used as antiseptics, but that solutions of hypochlorous acid have not been generally employed, although there is evidence that the chlorine water of the old *British Pharmacopoeia* owed its antiseptic power to the presence of hypochlorous acid in solution. The experience related in this report and that of other surgeons show that hypochlorous acid can be

applied in the treatment of septic wounds to an extent hitherto unsuspected. This general conclusion, it is pointed out, is confirmed by observers who have worked with dilute solutions of sodium hypochlorite.¹

The report contains notes on 257 cases; 199 were civil cases and the remainder military; the cases were selected to show the applicability of the method to the treatment of wounds, both recent and those in which sepsis had been established for at least a week, and in some cases for months. Of the civil cases 100 were treated in the outpatient department of the Royal Infirmary by Mr. J. M. Graham and Mr. Jardine. They consisted of lacerated and contused wounds, cuts, septic ulcers, abscesses, whitlow, etc. Upon these cases the following observations are made:

Of these, 67 never showed sepsis; 23 were septic when they were admitted to the department; 10 became septic after treatment, but experience showed that the cause of this was insufficiency in the application of eusol—for example, one dry dressing in twenty-four to seventy-two hours.

Special note was made in 10 cases in which an experimental first field dressing was applied with the view of testing its power of preventing sepsis. It consisted of a pad of gauze, in the centre of which were placed 2 grams of dry eupad. The powder was moistened by fluid discharge from the wound, or where the wound was dry a little water was poured on the dressing. It was covered only by the bandage. The purpose was to test the disinfecting power of the hypochlorous acid gas given off from the moistened eupad.

This treatment was completely successful except in three cases. In one of these the patient returned after twenty-four hours, when the wound was found clean and a eusol dry dressing was applied. The patient then absented himself for seven days, and at the end of this period he returned with the wound septic.

In the second case, a contusion of the scalp in a child 5 years of age, the wound remained clean for three days. It was then being treated with a dry dressing of eusol; this was insufficient to prevent the onset of sepsis, but it was cured by eusol soaks.

In the third case the wound became infected because the patient removed the dressing.

This subject deserves further investigation, but it can be adequately dealt with only in the field—for example, by the regimental medical staff or the field ambulance medical officers.

The military cases comprised superficial wounds, deep flesh wounds, fractures, and injuries to bone, including necrosis, and septic synovitis.

The wounds were all septic when the patients reached the hospitals. Except in a few cases of recent accidental wounds, the interval between the receipt of the wound and entry to hospital varied from one to three weeks; in many cases the interval was longer, treatment having already been carried out in another hospital.

GENERAL CONCLUSION.

The following are the conclusions drawn by the Committee:

"Further clinical experience of eusol in a great variety of cases has proved it to be a non-toxic, non-irritating, and efficient antiseptic.

"Nothing in this experience has been more striking than the fact that while it is highly destructive to bacteria, it is non-toxic to the tissues. In eusol free hypochlorous acid is the most essential ingredient, but there is present also a sufficient quantity of boric acid of calcium to give the solution a reaction alkaline to litmus. This feebly alkaline solution can be introduced into wounds or serous cavities with perfect safety. It can even be left in such cavities in quantity without any harmful effect. In lacerated and contused wounds, and in compound fractures such as are met with in military practice, it is the most efficient antiseptic we possess.

"It is most efficacious during the period of what might be termed progressive sepsis. Some surgeons have emphasized the benefit of modifying the treatment when sepsis is subsiding or has ceased. The granulations form after a period of two to three days, and rapidly cover the surface of the wound. Any tendency to superabundant growth of granulations, and consequent delay in healing, can be counteracted either by so applying the eusol that the serous discharge is reduced to a minimum and the wound is kept dry, or by discontinuing eusol and using other dressings appropriate for healing wounds. In any event the sepsis is by this stage completely under control.

"The freedom which can be exercised in the application

¹ Dakin, BRITISH MEDICAL JOURNAL, 1915, vol. ii, p. 318; Bowly, *ibid.*, p. 921.

of eusol, and the rapid action which it has in arresting the sepsis and discharge of an infected wound, led to experiments on the effect of eusol on the blood. Following on this, eusol was employed in the treatment of general septic toxæmia by intravenous injection.

"This method was first made use of by Lorrain Smith, Ritchie, and Rettie,² in a case of grave puerperal septicæmia, and the result was the recovery of the patient. They have applied the treatment in other similar conditions. In several cases toxæmia has been successfully overcome, and although such a result has not been uniformly attained, the safety of the method justifies its being applied in the diseases referred to in their preliminary communication. Intravenous injection has also been applied with success by Captain Fraser and Captain Bates in cases of acute toxæmia secondary to gas gangrene.³

"Further research is now being carried out on the development of the subject foreshadowed by these investigations."

SOME PRACTICAL CONSIDERATIONS.

Some practical considerations are developed in an appendix, which is as follows:

"Hypochlorous acid is an extremely active bleaching agent, and it should therefore not be brought into contact with coloured fabrics. Further, if cloth is kept in the solution for some time, its fibres are made brittle from destruction of the texture. Any towels, etc., which become wetted by the lotion should be forthwith rinsed in a large quantity of water to remove the acid as rapidly as may be. It also is corrosive to metals: instruments, needles, etc., should be carefully treated, else they will rust.

"The lotion is exceedingly inexpensive. The ingredients are procurable everywhere at a slight cost, and the preparation is a very simple process. At the present time especially it will be found that the introduction of eusol will effect economy in the outlay for the treatment of septic wounds—a point of considerable importance since phenol and its derivatives are becoming increasingly difficult to procure.

"Finally, it may be useful to set forth the details for preparing the antiseptic:

"Eupad powder is composed of equal weights of boric acid and bleaching powder. The boric acid is in sufficient excess to set free the hypochlorous acid in the solution. The bleaching powder should be dry and should contain 28 to 30 per cent. available chlorine.

"The solution eusol is prepared as follows: Add to 1 litre of water 25 grams of the powder; shake well; allow it to stand an hour; filter. The clear solution is eusol and contains about 5 per cent. hypochlorous acid. If the bleaching powder is old or not up to the strength given above, use a larger quantity of the powder. A rough and ready method of preparation is to add $\frac{1}{2}$ oz. of the mixed powder to 1 pint of water, stir or shake, and allow the sediment to settle. In cold weather the solution will keep its strength for three weeks. In hot summer weather it loses its strength more rapidly and should not be kept more than one week. It keeps best in bottles of coloured glass in a dark cupboard.

"For use as a lotion the solution must be warmed. This may be done by placing the bottle in a basin of hot water, or the solution may be made double strength (50 grams to the litre) and diluted with an equal volume of hot water. The double strength solution will not keep its value for more than two days."

ROYAL MEDICAL BENEVOLENT FUND.

(Concluded from page 134.)

The following is a continuation of the summary of cases relieved by the Committee at its meeting on December 14th, 1915:

L.R.C.P.Edin., aged 58, who practised at Old Kirkpatrick, N.B. Is suffering from spastic paralysis. Lives with a sister who has to earn a living by taking in boarders. Only income is that given by the Fund. Has one son, aged 19, who is studying for a dentist, and his fees being paid by the Fund and Guild. Relieved eleven times, £132. Voted £12 in twelve instalments.

Widow, aged 56, of L.S.A.Lond. who practised at Islington and died in 1905. Applicant was left with two sons, who helped to keep her. The elder one, however, died in March, 1915, and the other joined the army, and has been missing since April, 1915. She is now keeping house for two young nephews. Relieved eight times, £128. Voted £18 in twelve instalments.

Daughter, aged 47, of M.D.Edin. who practised at Southampton and died in 1886. Applicant's only income is £25 per annum from a charity and friends; she is suffering from chronic neuritis and quite unable to continue her work as a nurse. Relieved twice, £14. Voted £12 in twelve instalments.

Daughter, aged 71, of M.D.Edin. who practised in Somersetshire. Applicant lost all her income through unfortunate investments. Used to earn a little by painting, but cannot obtain any commissions at present. Relieved three times, £42. Voted £3, and referred to the Guild for report.

Widow, aged 66, of L.R.C.P.Edin. who practised at Port Carlisle and died in 1893. Applicant was left quite unprovided for, with five children, none of whom are able to help. Has recently had breast removed for cancer, and otherwise health very bad. Elected to annuity of £10 by another charity this year. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 60, of M.R.C.S.Eng. who practised in Liverpool and died in 1895. Applicant is a trained nurse, but in consequence of ill health is not always able to work. Relieved six times, £42. Voted £12 in twelve instalments.

Daughter, aged 57, of M.R.C.S.Eng. who practised at Hammer-smith and died in 1908. Owing to ill health the applicant is unable to obtain employment. Has no income, but receives occasional gifts of clothes and food from friends and help from the Guild. Relieved eight times, £104. Voted £18 in twelve instalments.

Widow, aged 54, of M.R.C.S.Eng. who practised in Wiltshire and Devonshire and died in 1914. Applicant was left unprovided for at husband's death, who was an annuitant of the Fund. Receives a little help from friends, but not sufficient to keep her, and unable to obtain suitable work. Relieved three times, £16. Voted £12 in twelve instalments.

Widow, aged 56, of L.S.A.Lond. who practised at Limehouse, E., and died in 1914. Applicant was left unprovided for, with two daughters now aged 21 and 23 years, but neither living with their mother, or able to help much. Applicant's health very indifferent, and only able to earn a little by needlework. Relieved ten times, £58. Voted £12 in twelve instalments.

Widow, aged 48, of M.R.C.S.Eng. who practised at Hexham and London and died in 1908. Applicant dependent on boarders, which is very precarious, and what she can obtain by needlework. Has four stepchildren and one daughter of her own who lives with her, but earns very little in consequence of bad sight. Relieved six times, £72. Voted £12 in twelve instalments, and referred to the Guild.

Daughter, aged 69, of M.R.C.S.Eng. who practised at Cheltenham and died in 1879. Applicant's health is very bad, suffering from rheumatism and defective sight. Only income two small annuities, and not quite sufficient to live upon. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 61, of L.R.C.P.Edin. who practised in Dublin and died in 1900. Was left unprovided for, but was helped a little by son, who has recently died; also earns a little by needlework. Health now very indifferent. Relieved three times, £30. Voted £10 in two instalments.

Daughter, aged 69, of M.R.C.S.Eng. who practised in London and died in 1875. For forty years earned her living as a governess, mainly abroad, and for the last ten years in Russia. Her life savings were in a bank in Berlin, and she has not been able to obtain any of them. Has recently been able to earn a little by sewing, but not enough to live upon. Relieved once, £12. Voted £12 in twelve instalments, and referred to the Guild.

Daughter, aged 60, of M.R.C.S.Eng. who practised in London, and died in 1877. Applicant's only certain income a small pension from another charity. Before the war she earned a little by teaching music. Health has been very unsatisfactory of late. Relieved once, £10. Voted £10.

The claims on the fund show a constant increase month by month. At the last meeting the Committee had a record number of applications, and only a balance of £42 to meet them with. Grants were made to the extent of £448. To meet this deficit the reserves, which had already been reduced by £500, will have to be further drawn upon. Unless further support is quickly forthcoming, the Committee will have no choice but to restrict its operations, and that in the face of ever-growing claims. Subscriptions may be sent to Dr. Samuel West, the Honorary Treasurer, at 11, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild appeals for gifts of secondhand clothing, boots, and shoes in good condition, also household linen. The gifts should be sent to the Secretary, Royal Medical Benevolent Fund Guild, 43, Bolsover Street, W.

THE Eugenics Record Office, which has its head quarters at Cold Spring Harbor, Long Island, New York, has begun the issue of a bimonthly bulletin, entitled *Eugenical News*, to report its work. It has trained a number of persons engaged in social and eugenical research, and the investigation of family histories is conducted under its direction by a number of other agencies.

DAYLIGHT TREATMENT.

M. DASTRE proposed some time ago to apply the term "biotic" to the action of light on living tissues, and the word seems convenient. The effect of sunlight on plants is one of the commonest observations in nature, as is also the fact that diffused sunlight may be more wholesome for them than direct. It is possible to have too much of a good thing. In a vague way it has been recognized that sunlight might be good for animals also. Lately we have heard a good deal about the therapeutic effect of sunlight and are and incandescent lamps; wonderful powers have been attributed to the ultra-violet rays, and the x rays have been shown to possess great virtue, so that as heat, general or local, is perhaps the oldest of all prophylactic and curative agencies, we are now using rays all the length of the spectrum, though below the ultra-violet there is a long gap, as to which, indeed, even the physicists know very little. Physiologically in both plants and animals light probably exerts its action wholly or mainly through the natural pigments chlorophyll or haemoglobin, green being almost as absorbent, and red only a little less absorbent, than black. The effects observed may be due either to direct absorption of energy, or to an excitation effect on the protoplasm. Sunlight, and ultra-violet rays unfiltered or having only undergone a small amount of filtration, are fatal to bacteria, but so thin a layer protects them that even direct sunlight ceases to be lethal when it has to travel through only 1 mm. of the tissues.

Dr. Miramond de Laroquette reported recently to the Académie de Médecine in Paris¹ the results of a long series of observations carried out from 1910 to 1914 on animals and plants in conservatories with coloured glasses. His general conclusion is that the biotic action of light is not due exclusively, or even principally, to what are commonly called the chemical rays. He found that in spite of the fact that the chemical effect of blue light is nearly equal to that of white light, blue has very slight biotic effect, much less than yellow and a little less than red. All parts of the solar spectrum, the infra-red light and the ultra-violet, appeared to benefit plants, but the most active was light, and of the light rays the most active was yellow, which has little chemical action, but is highly illuminating and heating. Long exposure to strong sunlight has an irritating effect on tissues, and produces erythema in man; if intense and prolonged it may cause dehydration and coagulation of the protoplasm of cells, and there is reason to conclude that these effects are mainly due to the chemical rays. The bactericidal action of light is only to be observed when the bacteria are in layers very thin or easily dried. Cultivations of the colon and paratyphoid bacilli, and of streptococci and staphylococci in liquid mediums resisted long and strong irradiation; some lived in Dr. Laroquette's conservatories for as long as six months, even when under ordinary white colourless glass, which only cuts off a very small part of the ultra-violet. If more than 1 mm. deep in the tissues, bacteria are protected, for irradiation

strong enough to kill them destroys the cells also. Dr. Laroquette concludes that any therapeutic results are primarily biotic, and that any destruction of bacteria is secondary, due to the stimulation of the defensive powers of the tissues.

Nevertheless he is a strong advocate of treatment of the wounded by daylight; after exposure for a few days to sunlight suppuration diminishes, wounds assume a healthy aspect, and cicatrization proceeds rapidly. That the treatment is not more generally adopted is due, he thinks, to certain misapprehensions. One mistake made is to expose patients to direct sunlight over too large a surface and for too long a time. Another mistake is to suppose that direct sunlight is necessary at all. He argues that it is not, and asserts that a large number of experiments and clinical observations have convinced him that light filtered through ordinary window glass does not lose its biotic powers, that it may still irritate the tissues, and also exercise some part of the small bactericidal power possessed by the unfiltered sunlight. He holds that exposure to diffused light, though it acts less rapidly, is not less effective if sufficiently prolonged. The light treatment of wounds should, he considers, be carried out in large, well-ventilated conservatories, with walls and roofs of ordinary glass. The temperature should be maintained at about 27° C. (80° F.), and at that temperature large surfaces of the body can be exposed without inconvenience. The light can be regulated by screens or blinds, as in a photographer's studio, or if the sun is shining brightly, by yellow screens. When the light is bad it can be concentrated on the wounds by reflectors or lenses. Dr. Laroquette declares that the results he got at the Maillot Hospital, Algiers, among the wounded from Morocco in 1912 to 1914 were most satisfactory, and that many surgeons who, during last summer, used heliotherapy in France are convinced of its efficacy.

As there seem still to be many who are sceptical as to the injurious effect of direct sunlight when a large surface of the body is exposed to it, we may take the opportunity of mentioning a paper by C. Römer,² in which he condemns his countrymen for their indiscriminate resort, especially when suffering from nervous debility, to sun baths. The public, he says, use them irrationally and immoderately, owing to the growth of a superstition that the sun possesses the primary sources of healing for every evil. In special sun and air institutions in every large town persons of every age and with every kind of disease expose themselves by the hour to the direct rays of the sun. To one such institute in Hamburg as many as 18,000 may go on a Sunday in the summer. The chief results of the exposure of the whole body to the sun are a rise of temperature and increase in metabolism. Though in small doses and under certain conditions this treatment may, he thinks, possibly be beneficial, yet, indulged in as a fad, it is harmful, particularly for the subjects of nervous instability. Its devotees are mainly recruited from among the tired, flabby, anaemic workers in offices and factories, where the day is spent in dark and unhealthy surroundings. To make up for these drawbacks, the workers take overdoses of sunlight when they can, with the result that they become exhausted, irritable, sleepless, and unfit for work. Not infrequently by the end of the summer they have to go into hospital. Römer mentions the case of one lad, aged 16, who had indulged in a sun bath on July 19th for several hours without any covering to his head. Afterwards he suffered from

¹ Bull., T. lxxiv, p. 549.

² Deut. med. Woch., July 8th, 1915.

severe headache; on admission to hospital on July 24th, he showed nothing abnormal, apart from marked pigmentation and irritation of the skin. There was no fever or cervical rigidity, and the pulse was slow. Lumbar puncture, which yielded clear, sterile fluid under a pressure of 320 mm. of water, was instantly followed by cessation of the headache, and the patient was discharged on July 28th perfectly well. In another case a lad, aged 16, had spent the whole day of July 12th in the sun without any covering to the head. The headache which followed still persisted on July 20th, when he was admitted to hospital with the diagnosis of meningitis. The temperature was 38° C., and the pulse was soft and rapid; Kernig's sign was positive, and cervical rigidity was demonstrable. There was no mental disturbance, and examination of the eyes and urine was negative. Lumbar puncture yielded clear, sterile fluid under a pressure of 280 mm. of water. The pain diminished at once, and next day the fever, cervical rigidity, and Kernig's sign had disappeared. On July 23rd the pressure of the cerebro-spinal fluid had fallen to 150, and on July 27th to 110 mm. of water.

CEREBRO-SPINAL FEVER.

A NUMBER of interesting conclusions are reached by the authors¹ of a recent paper on 161 cases of cerebro-spinal fever treated during 1915 at a hospital located, apparently, somewhere in France. Dealing first with the problem of carriers of the meningococcus, they argue that the spread of the infection is not necessarily caused by the immediate contacts. They do not think that the disease can properly be called contagious, because no case occurred and no carriers were found among the nurses, nursing orderlies, or medical officers in attendance on the patients, though quite a number of carriers were detected among units in the field. The diagnosis is often difficult early in the disease, except in the very acute cases. Cerebro-spinal fever is differentiated from influenza by the relatively slow pulse of high tension, the frequent hyperaemia of the ciliary region of the sclerotic, the dry and dirty tongue, the high leucocytosis, and generally also by the changes in the cerebro-spinal fluid, that characterize cerebro-spinal fever. In enteric fever the onset is less abrupt, there is a leucopenia, and the evidence obtained by lumbar puncture is conclusive. In two cases acute mania closely simulated cerebro-spinal fever; the diagnosis here was made by lumbar puncture. In fact, the authors lay great stress on lumbar puncture in the diagnosis of cerebro-spinal fever; it was performed in 160 cases, and showed the presence of many polymorphonuclear leucocytes in the fluid withdrawn in every case, with intracellular diplococci in 117 instances; both small and large lymphocytes were also increased in every instance. The occurrence of ocular signs and symptoms—such as blepharitis, purulent conjunctivitis, keratitis, optic neuritis, ptosis, squint, and nystagmus—is said to be of bad prognostic import, as is also loss of control over the sphincters if it is more than transient. Among the complications noted were acute nephritis in nine cases, suppurative arthritis of the knee in two patients (cured by repeated aspiration), hyperpyrexia in two fatal cases, and acute or chronic hydrocephalus was seen very frequently. As for treatment, the patients were nursed in a large and airy ward, and were put out on a balcony in the open air whenever possible. Frequent lumbar puncture

after the administration of a little pure chloroform was the main line of treatment. This was repeated daily for four or five days, and then every second day for about a week unless the patient was convalescent, when the puncture was discontinued, or seriously ill, when it was repeated daily. With this treatment alone 21 out of 43 patients died. Other patients received this treatment combined with vaccine or serum treatment; except in the case of the living vaccine (29 cases, 13 deaths) the mortality here was higher. This uniformly high mortality is ascribed to the fact that many of the patients did not come under treatment till the fifth or even the eighth day of the disease. In four cases trephining for decompression was performed, in one with a successful result. One patient recovered after the fever had lasted 141 days, and another after 96 days of pyrexia. One patient—a young woman who had been visiting her husband lying ill with meningitis for some weeks—had a hysterical attack closely simulating cerebro-spinal meningitis, with headache, a temperature of 101° F. and a pulse of 68, retraction of the head and stiffness of the neck, photophobia, erythematous blotches on the abdomen, ankle clonus and exaggerated knee-jerks; a flexor plantar response, and a doubtful Kernig's sign. Lumbar puncture was performed thrice, and yielded a normal cerebro-spinal fluid on each occasion. Recovery was rapid. The authors remark that no satisfactory method for the speedy isolation or differentiation of the meningococcus has yet been devised, a fact that should not be overlooked when the diagnosis of carriers of the meningococcus is being considered with a view to checking the spread of the disease.

A novel aspect of its etiology is introduced by Dr. Hort, in a paper printed on another page of this issue. He does not believe that Weichselbaum's meningococcus is the causal agent of cerebro-spinal fever. His experiments lead him to think that the true infecting agent is a very minute organism capable of passage through the pores of a Chamberland F filter; he holds that the meningococcus itself is incapable of reproducing the disease, but is constantly associated with this filterable virus that does cause it, and has hitherto been overlooked by investigators of the pathogenesis of this form of meningitis. That some connexion exists between the new virus and the old meningococcus with which we are all familiar seems a natural conclusion. Possibly, as Dr. Hort suggests, the two are but different phases in the life-history of a single causal micro-organism. The point is one that can safely be left to the future for elucidation. Dr. Hort's paper and his views on the etiology of cerebro-spinal meningitis will be read by bacteriologists with interest, if not, perhaps, with immediate acquiescence and approval. The many points he deals with are naturally in need of further investigation and confirmation, on the lines pointed out by himself, before they can expect to command general acceptance.

THE INSURANCE COMMISSIONERS AND MEDICAL RECRUITING.

THE circular issued by the Insurance Commissioners for England and Wales to Insurance Committees with regard to medical recruiting (see SUPPLEMENT, January 8th, p. 5) is being construed, it would appear, by some Insurance Committees in such a literal way that there is a danger that quite unnecessary obstacles may be put in the way of panel practitioners joining the army. Though the Commissioners expressed their anxiety that nothing of the sort should

¹ Lieutenant-Colonel E. A. Bourke, Captain R. G. Abrahams, and Major S. Rowland: *Journal of the Royal Army Medical Corps*, London, 1915, xxv, 633.

occur, their circular, we fear it must be admitted, lends itself to the interpretation that the convenience of the insured population must at present take preference over the requirements of the army so far as medical service is concerned. That this interpretation has been put on it by more than one Insurance Committee appears from their acts, and the work of obtaining medical recruits by the medical war committees, which was already hampered quite enough by the private difficulties of practitioners, will be made far more difficult if all the suggestions of the Commissioners are to be carried out in the literal spirit which these committees show. The Commissioners reminded Insurance Committees that the panel doctors are under contractual liabilities, and a hint is given that for the present, at all events, the contracts must be strictly enforced. An example showing the interpretation which may be put on the circular is afforded by a letter addressed by the Insurance Committee of the County of Middlesex to the panel practitioners of its area. The Committee seems to agree with Mr. Lambert, M.P., who "does not see that the war makes any difference." It asks the recipient to "remember that your agreement provides that all treatment shall be given by you personally, except where you are prevented by urgency of other professional duties, temporary absence from home, or other reasonable cause, and that you will to the best of your ability provide that when you are so prevented some other practitioner will give attendance as deputy on your behalf." After this the Committee goes on to say that "before releasing a practitioner for military service it must be satisfied (1) that there is no likelihood that the absence of the doctor in question will render the panel service no longer efficient, either generally or in any particular locality, due regard being had to the seasonal variation of sickness incidence; and (2) that satisfactory arrangements are made for carrying out the absentee's duties."

It is not too much to say that in all probability the mere mention of these guarantees will already have deterred more than one panel practitioner from offering his services to the army, and if the terms of the letter are enforced in their obvious sense it will put almost insuperable difficulties in the way of the medical war committee or committees for the Middlesex area.

Practitioners throughout the country have made the best arrangements they could to safeguard the practices of those practitioners who are absent on war service. This was entirely an act of free will. As a general rule the arrangements involve that the practitioners who remain at home should undertake to do a vast amount of additional work for half the ordinary fees, the other half going to the absentees. So long as this was a purely voluntary arrangement it would have worked well, but now the Commissioners make a pronouncement which is interpreted to mean that Insurance Committees are set up as judges as to whether these voluntary arrangements are satisfactory. In other words, since it is practically impossible at present on any large scale to obtain locumtenents, Insurance Committees, believing that they are acting in accordance with the instructions of the Insurance Commissioners, are, by demanding the stringent guarantees mentioned above from any panel practitioner who would be willing to join the army, not only appropriating as a right what was intended as an act of grace, but are assuming a right to criticize a free gift. If the Commissioners had stopped at suggesting friendly conferences between local medical war committees, panel committees, and insurance com-

mittees, there is little doubt that efficient arrangements for continuing to provide an adequate medical service for the insured would have been made; but when they go further and suggest measures which can be interpreted as justifying the blunt letter of the Middlesex Insurance Committee, reminding panel practitioners that they must carry out their contract to the letter, and demanding that a would-be recruit must give guarantees against such contingencies as seasonal variation of sickness incidence, they are, no doubt unwittingly, putting serious hindrances in the way of medical recruiting and unnecessarily hampering the work of the medical war committees.

It might have been supposed that, having seen the hideous iniquities to which it has led, the exponents of State socialism would have been ready to show some degree of modesty in using the letter of the law to enforce their doctrines on an unwilling people. It seems that this was too sanguine an expectation. To them we commend the perusal and reperusal of the book by the Right Hon. J. M. Robertson reviewed in another column. They can hardly flatter themselves that he is a prejudiced witness.

INTRAVENOUS INJECTION OF HYPOCHLOROUS ACID IN THE TREATMENT OF TOXAEMIA.

THE four cases¹ in which the intravenous injection of hypochlorous acid in severe toxæmia has been followed by very remarkable improvement will direct attention to this method. It is important, therefore, to point out that among the problems which are raised by these investigations there is one which should receive the special attention of observers—namely, the composition of the solution which contains the antiseptic. The solution *eusol* contains several ingredients, the chief of which are hypochlorous acid and calcium bichlorate. According to the original statement of Lorrain Smith, Drennan, Rettie, and Campbell,² the solution of *eusol* contains hypochlorous acid 0.54 per cent. and calcium bichlorate 1.28 per cent., with a small quantity (0.17 per cent.) of calcium chloride. The hypochlorous acid is estimated by titration with N/10 arsenious acid. In virtue of the balance which is established in this solution the reaction is faintly alkaline, while the hypochlorous acid is to a large extent free. It has been shown by experiment that considerable quantities of this solution can be injected into the veins of normal animals with impunity. On the other hand, a solution of pure hypochlorous acid cannot be injected, as it coagulates the blood; nor can a dilute solution of sodium hypochlorite be injected, since it causes hæmolysis.³ Further investigations will show the extent to which the intravenous injection of *eusol* can be applied in the treatment of toxæmia in the human subject. It will be noted that in all the cases the solution actually injected was made up in normal saline. The solution employed by Captains Fraser and Bates consisted of *eusol* containing 0.5 per cent. of hypochlorous acid to which was added 8.5 grams of sodium chloride per litre and the solution was carefully standardized before injection. In two cases (C and D) the quantity injected intravenously was 40 c.cm.; in a third (E) 70 c.cm. In the case of puerperal fever reported by Lorrain Smith, Ritchie, and Rettie the quantity was 100 c.cm. of *eusol* made up in normal saline and the temperature 98.4° F. It appears that the rate of injection (10 c.cm. per minute) is an important point.

THE NEW LIGHTING RESTRICTIONS.

THE difficulties which it is feared the new lighting restrictions will create for medical motorists were brought to notice in the House of Commons by Mr. Perkins on

¹ Lorrain Smith, Ritchie, and Rettie, *JOURNAL*, November 13th, 1915, p. 715; Fraser and Bates, *JOURNAL*, January 15th, 1916, p. 85.

² *JOURNAL*, July 24th, 1915, p. 129.

³ Dakin, *BRITISH MEDICAL JOURNAL*, August 28th, 1915, p. 319.

January 19th, when he asked whether, in view of the difficulties of medical men living in country districts who frequently had to drive themselves long distances after dark to visit patients, the desirability of exempting their cars from the new lighting order would be considered. The Home Secretary (Mr. Herbert Samuel), in his reply, expressed the opinion that the effect of the order had been misunderstood in some quarters. The use of headlights was prohibited in certain areas, but the limits of size and power for side-lights had been fixed so high as to allow a good driving light on country roads at night. The order, he added, was settled in consultation with expert motorists, and had been generally accepted. We understand that experiments have shown that if the side-lamps are placed above the mudguards and fairly well forward the lighting of the road is much improved; the Home Office takes no objection to this position so long as the lamps show the full width of the car. In its reply to the letter addressed to it by the British Medical Association on December 31st, 1915 (SUPPLEMENT, January 15th, p. 10), it pointed out that in some cases motorists might be unable to obtain the full illumination the new order allows with the lamps they already possess, but added that, on the whole, a better driving light was permitted under the new order than under the orders previously in force. The authorities lay great stress upon the necessity of so altering the side-lamps as to obtain from them the full amount of light allowed by the order, and it is said that much of the dissatisfaction shown by motorists in regard to the new restrictions will disappear if careful attention is given to this detail. Some of the manufacturers are selling at quite a cheap rate a fitting which allows oil lamps to be converted into acetylene lamps.

"THE CRIMES OF THE GERMAN ARMY."

The special illustrated supplement of the *Field*, entitled, "The Crimes of the German Army" (1s.), will fulfil the high expectations of those who possess the supplement it published last February. France, her ambassador in this country tells in a letter of approval, desires that the truth should be universally known. That is all, and it is enough; not Raemaekers' green devil could devise any forms of cruel, cowardly, and bestial crime not committed by the Germans and their allies during the last eighteen months. The crimes are related in this publication from official documents compiled from the statements of survivors, and the official notices, or unguarded statements in diaries never meant to be published, of the criminals. These are some of the headings: "Crimes against women and children," "outrages against civilians," "burning, loot, and pillage," "massacres," "the use of civilians as screens," "killing or mutilating the wounded," "outrages on the Red Cross." It is well to have these deeds brought together in an accessible form, because already the Germans and their hirelings are beginning to deny them, not because they are not true, but because, according to a crazy apriorism, they cannot be true of a nation some of the members of which in the past have written beautiful music. The publication is copiously illustrated by photographs of destruction and cruelty, and of the wooden idols the Germans have erected, together with studio portraits of the gods in uniform. It contains also reproductions of pictures published in German newspapers, including a self-revealing drawing of the panic supposed to have occurred among the women and children on the quays (!) of Scarborough. It was a happy idea to scatter through the articles reproductions of the woodcuts of Holbein's "Dance of Death," engraved early in the sixteenth century. The historian of the future will give his verdict from the official documents, which are accumulating rapidly, but the appeal which Mr. T. A. Cook makes in his preface is to the people of to-day, that, whether belligerent or neutral, there shall be recalled to them the indisputable facts they have read piecemeal in the daily papers. The facts are damning, yet they are

excused by German men of science such, to name only a few whose names are best known, as Emil von Behring (Marburg), V. Czerny (Heidelberg), W. Erb (Heidelberg), Ernst Haeckel (Jena), Gustav Schwalbe (Strassburg), Wilhelm Wundt (Leipzig), Rudolf Kobert (Rostock), and August Bier (Berlin).

PASSPORT DECLARATIONS.

THE proceedings taken against Dr. A. H. Vassie, of West Hampstead, to which we referred on p. 945 of our issue of December 25th, 1915, concluded at the Old Bailey on January 14th in his acquittal of the charge of making a false declaration for the purpose of enabling a person to obtain a passport. As is probably well known, the Foreign Office requires all applications for passports to be accompanied by a form of recommendation signed by a British subject to the effect that the applicant is to his "personal knowledge a fit and proper person to receive a passport." Apparently, on August 3rd, 1914, a patient whom Dr. Vassie had known for many years introduced his niece, with the request that the doctor should sign her recommendation for a passport. Dr. Vassie ascertained from her that she was anxious to go to Germany in order to nurse her mother, who, she said, was seriously ill, and after putting a series of questions, all of which were answered willingly and satisfactorily, Dr. Vassie signed the form of recommendation, and a passport was issued by the Foreign Office on the following day. In July of last year the woman was arrested on a charge under the defence of the realm regulations. Inquiries were made of Dr. Vassie, as the person who had recommended her for a passport, with the result that proceedings were taken against him. The question which had to be decided by the jury at the Old Bailey was, had Dr. Vassie any "personal knowledge" as to the fitness of the applicant to receive a passport? The jury found that he had, and, as we have already mentioned, acquitted the doctor. The case is of some little interest to members of the medical profession, many of whom must frequently be asked to sign recommendations for passports, and the question which at once arises is, what extent of personal knowledge must a man have before he signs such a recommendation? In Dr. Vassie's case the jury considered that his seeing the applicant and putting a series of questions was sufficient; and although the finding of a jury in one case is no authority affecting the decision of another, even if the facts are identical, yet it is probably safe to assume that ordinarily no jury would convict where such precautions had been taken. The question is, after all, rather one of ordinary care and diligence than of anything else. A person who signs a passport recommendation must realize that by so doing he is becoming a sort of guarantor for the applicant, and that he is enabling him or her to obtain a passport which he or she could not otherwise have. He must therefore satisfy himself, so far as he is able as an ordinarily careful and prudent man, that the applicant he proposes to recommend is a fit and proper person to receive a passport, and unless he is satisfied he should refuse to sign.

CREMATION IN THE UNITED STATES.

THE Cremation Association of America held its third annual meeting at Buffalo, New York, on August 26th and 27th, 1915, when Dr. Hugo Erichsen of Detroit, the President, delivered an address in which he said that cremation had received the formal approval of the American Medical and American Public Health Associations. He urged the adoption of a vigorous propaganda to enlist the practical sympathy of persons having weight in their respective communities, and suggested the raising of a fund for that purpose by means of legacies of 1 per cent. on the estates of deceased members. He called on the medical press of America to pay more attention to cremation, saying that as a physician he was deeply ashamed of the fact that they could

not point to a single medical periodical in the States that could compare in this respect with the *BRITISH MEDICAL JOURNAL*, which had championed incineration for years. The American Cremation Association had, he said, grown steadily. The growth in 1890-94, as compared with 1885-89, was 25 per cent.; in 1895-1900, 39 per cent.; in 1900-4, 44 per cent.; and in 1905-9, 63 per cent. Mr. S. Frank Balcom, of Indianapolis, said that before 1884 there had been but a score of incinerations in America. Between that year and 1888 Le Moynes crematorium had been followed by structures in New York, Buffalo, Pittsburgh, Philadelphia, Detroit, Los Angeles, Cincinnati, and St. Louis. About that time cremation societies were formed, and a good many members of the medical profession became interested in the movement. A table of statistics, presented by Mr. Samson to the Indianapolis Convention, showed that eleven of the fifty-three crematories in the States were in California, and that about one third of all incinerations in the States had been carried out in California. This had been due to what might be called expediency. Many persons who failed to regain their health in that State and died there were incinerated, and the ashes returned to their former homes. Mr. Balcom suggested the formation of an incorporated body of the Cremation Association of America, with a central office in Washington from which propagandist literature could be distributed. Certificates might be issued, good for incineration at any crematory in America, on payment of, say, from £10 to £50, the ashes to be deposited under perpetual care if desired in a national columbarium. A resolution endorsing a petition addressed by Dr. Stefan Ulbrich, a Roman Catholic physician of Reichenberg, Austria, to the Congregation of the Inquisition at Rome, was passed. That petition asked the Holy See to rescind the decrees forbidding incineration to members of that Church. These decrees were based on the premiss that cremation was a tenet of Freemasonry, but it was pointed out that cremation was not a dogma of the Masonic order. Copies of the resolution were sent to Archbishop John Bonzano, Apostolic Delegate to the United States. One of the most interesting communications made to the meeting was a paper by Mr. J. Franklin Meehan on the planting and care of crematory grounds. Dr. Erichsen was re-elected president, and he was also chosen to be a delegate of the association to the next International Cremation Congress, which is to meet "shortly after the war."

WINTER CLIMATE OF THE EASTERN MEDITERRANEAN.

In his presidential address to the Royal Meteorological Society Major H. G. Lyon, F.R.S., said that the returns from the large number of meteorological stations which had been in operation during the last fifteen to twenty years gave much accurate and detailed information as to the conditions prevailing at different seasons of the year in the Eastern Mediterranean. The conditions vary from the true continental climate of the Balkans, with low winter temperatures and moderate rainfall at all seasons, to the Mediterranean climate of Southern Greece and the Levant, with a hot summer and a strongly-marked rainy season in winter, characters which prevail in a more intense form in Egypt. Major Lyon said that the temperature in the Balkan region in winter was frequently very low, descending often below zero Fahrenheit. Frost occurred often in inland Greece and occasionally throughout the Eastern Mediterranean. The most severe weather occurred when anticyclonic conditions with clear skies and light winds prevailed in the Balkans; the air then fell to a very low temperature, and as a result streamed off the highland down into the low-lying Aegean Sea as a strong, cold northerly wind, which of course reached gale force. January was the coldest month, but February differed little from it, and the first

marked departure from winter conditions occurred in March. During the winter months the waters of the Mediterranean were from 5° F. to 10° F. warmer than the coasts, where, therefore, the winter climate was much milder than inland, but in March the difference became very small and disappeared at many places as the land was growing rapidly warmer. In winter rainfall was heaviest on the western shores of Greece and Syria, and markedly less on the eastern coast. The Balkan rainfall had a maximum in November, and afterwards decreased slightly, but was not heavy at any time; rain fell during the passage of depressions from the Mediterranean, which passed from west to east, bringing cloudy mild weather, rain and strong winds. Rainfall decreased southward, and in lower Egypt the amount was insignificant. The normal air circulation of the Eastern Mediterranean was simple in its general outlines. Northerly winds blew over Greece and the Aegean Sea, becoming north-westerly in the Mediterranean and westerly on the Syrian Coast. In Egypt northerly winds prevailed. This arrangement, which followed from the mean distribution of pressure in winter, was, however, greatly modified by the frequent passage of depressions along the Mediterranean from west to east. Many passed over the Balkans to the Black Sea and Southern Russia, causing strong southerly gales in the Aegean Sea, with rain and mild, unsettled weather for two or three days. Others crossed Greece and the Aegean, where, as they were approaching, strong southerly winds blew, which usually veered to the north-west on the following day. Others, again, passed to the south of Greece, sometimes skirting the Egyptian coast, and caused south-westerly gales and stormy weather in the Eastern Mediterranean and Levant, and northerly winds in the Aegean Sea. Northerly winds, which caused rough sea in the Aegean Sea during the winter months, were more frequent than southerly winds in the proportion of 2.5 to 1; and since many of these northerly winds were due to cold air pouring down from the Balkan highlands, the northerly winds might continue for a week at a time, while southerly gales rarely lasted for more than two days, unless a second depression was closely following the first.

We regret to announce the death, on January 25th, of Emeritus Professor John Wyllie. Dr. Wyllie was appointed professor of medicine in the University of Edinburgh in 1900, in succession to Sir Thomas Grainger Stewart, and retired owing to ill health in November, 1914. We hope to publish a biographical notice in an early issue.

The Council of the British Medical Association, at its meeting on January 26th, the first held since July, 1915, expressed its approval of the work done by the Central Medical War Committee appointed at the instance of the Representative Meeting, 1915, and of the measures it had taken and was taking to organize the medical profession in England and Wales to do its share in meeting the demands of the army, while safeguarding the interests of the public and of individual members of the medical profession as fully as the exigencies of the supreme struggle in which the British Empire is engaged permit.

The Financial Secretary to the Treasury (Mr. Montagu) informed a deputation representing the approved societies, on January 26th, that it had been decided to appoint an expert committee on the questions of the simplification and the finance of the Insurance Act.

The *Muenchener medizinische Wochenschrift* states that the reports circulated recently as to the serious state of the health of the German Emperor were greatly exaggerated. It adds that the physical fatigue and intense mental anxiety the Emperor has undergone since the war began has rendered him less able to resist minor illnesses.

Medical Notes in Parliament.

Central Medical War Committee.

MR. LYNCH on January 20th asked the Prime Minister whether he would take steps "to reorganize and recall to normal action the Statutory Advisory Board of the Army Medical Services, that it may resume regular meetings in its consultative capacity with a view to aiding the Director-General to a better utilization of the skill and experience which has been offered by medical men to the War Office, and to a more appropriate distribution of medical aid both for meeting the necessities of the military situation and for the needs of the civilian population." Mr. Tennant, in his reply, after pointing out that the Advisory Board was not statutory, referred Mr. Lynch to the answer given to Mr. Shirley Benn on November 25th (*BRITISH MEDICAL JOURNAL*, December 4th, p. 832); and to his written reply to the same member on January 12th (published in full in the *JOURNAL* of January 22nd, p. 140), where the matter had been dealt with at great length. "I may, however," Mr. Tennant continued, "add that, thanks to the patriotism of the medical profession, there is no present anxiety regarding the supply of doctors for the army, and the action of the Central Medical War Committee, with which the Director-General of the Army Medical Service is in touch, will be to carefully guard the interests of the civil population in this matter, the claims of whom have not been and will not be disregarded."

Mr. Lynch also asked whether during the last three years £600 had been paid yearly to each paid member of the Army Medical Advisory Board, and whether, seeing that since the beginning of the war the Board had held no meetings, the advisability of eliminating this expense would be considered if the Government desired that no formal meetings of that Board should be held. Mr. Tennant again replied by referring to the answers he had given to Mr. Shirley Benn on November 22nd and 25th (*JOURNAL*, December 4th, 1915, p. 832).

The Military Service Bill.

The Committee stage of the Military Service (No. 2) Bill was concluded in the House of Commons on January 20th. After the clauses of the bill had been disposed of considerable discussion took place on the first schedule, which enumerated the exceptions from the obligation of unmarried men to serve. The persons mentioned in the schedule as finally adopted are—

Exceptions.

1. Men resident in Great Britain for the purpose only of their education or for some other special purpose.
2. Members of His Majesty's regular or reserve forces, or of the forces raised by the Government of His Majesty's Dominions, and members of the Territorial Force liable for foreign service or who are, in the opinion of the Army Council, not suited for foreign service.
3. Men serving in the Navy, or the Royal Marines, or who, though not serving in the Navy or Royal Marines, are recommended for exception by the Admiralty.
4. Men in holy orders or regular ministers of any religious denomination.
5. Men who have left or been discharged from the naval or military service of the Crown in consequence of disablement or ill health (including officers who have ceased to hold a commission in consequence of disablement or ill health), and, subject to any provision which may hereafter be made by Parliament, men who have been discharged from the naval or military service of the Crown on the termination of their period of service.
6. Men who hold a certificate of exemption under this Act for the time being in force (other than a certificate of exemption from combatant duties only), or who have offered themselves for enlistment and been rejected since the fourteenth day of August, nineteen hundred and fifteen.

A protest was made against the inclusion of members of the Territorial Force who had not accepted liability for foreign service. Mr. Tennant said that the only men in the Territorial Force who would come under the bill would be those who were medically and militarily fit for foreign service, and of the vast number of men who had joined the Territorial Force at the outbreak of war, only a very small number would come in that category, for the Territorial Force had rallied splendidly to the call of the country. They would have the period up to the appointed

day to take upon themselves the foreign service obligation, and the Army Council undertook that, whenever possible, a man would be posted to a unit of his own corps, unless he desired otherwise. Men who were unmarried and fit for foreign service, but declined to take that obligation, would be discharged from the Territorial Force and would come into the general pool under the bill. Later in the discussion, Mr. Bonar Law added that the Army Council would have the right to keep these men in the Territorial Force without the necessity of going before a tribunal if the Council considered they were not suited for foreign service. The proposal to exempt members of the Territorial Force not liable for foreign service was rejected by 259 to 27. Colonel Yate proposed to omit Clause 4 of the schedule, which exempted ministers of religion, but the proposal was withdrawn after an appeal from Mr. Long on the ground that there was a shortage of such ministers at home.

Medical Men.

Mr. King moved to insert in the schedule the following words: "Men who at the time of the passing of this Act were fully qualified medical practitioners, or registered dentists, or students at any hospital." Mr. Raffan, in supporting the proposal, suggested that unregistered dentists should also be included. In the discussion Mr. Glyn-Jones said that every member of a profession needed in this country would be certain to get exemption under Clause 2, Subsection (1) (a):

2. (1) An application may be made at any time before the appointed date to the local tribunal established under this Act by or in respect of any man for a certificate of exemption from the provisions of this Act:

(a) On the ground that it is expedient in the national interests that he should, instead of being employed in military service, be engaged in other works in which he is habitually engaged or in which he wishes to be engaged.

The tribunal could exempt a person on the ground that it was expedient in the national interest that instead of being employed in military service he should be engaged in other work. Knowing the needs of a district and knowing that the medical profession was short, the tribunal would decide that it was expedient in the national interest that the applicant should be permitted to continue the work of his practice. He would certainly object to the exemption of unregistered dentists. Mr. Long admitted that those engaged in the administration of the public health laws and in watching the general condition of the health of the country, and making themselves acquainted with the supply of medical men and the calls made upon them, must view the present situation with grave anxiety. Only those who were constantly face to face with the official facts realized how tremendous had been the labours thrown on medical men since the outbreak of the war, and how unselfishly and heroically they had devoted themselves to their work. He knew men working day and night, many of them for no return, many of them for very little monetary return. The matter could not be viewed without anxiety and perhaps some misgiving, but, as Mr. Glyn-Jones had pointed out, there were two methods by which those who came within the purview of the bill might be released from service—the exemptions and the exceptions. Mr. Long proceeded to argue that it would be dangerous to include in the automatic exceptions all medical men and dentists, but it was obvious that all who belonged to those professions and whose services were required should, where the interests of the country demanded it, be retained in their practices and continue to do their present work. Their case was already met.

Sir Robert Finlay, as the representative of a constituency which had a great many medical men, said that he had listened to Mr. Long's remarks with satisfaction. The shortage of medical men even at the present time was undoubtedly extremely serious, but he thought that for practical reasons the course taken by the Government was right. A medical man who was wanted would get exemption, because it would be apparent that it was inexpedient that he should be taken away to serve in the army. Mr. King offered to withdraw the proposal, but leave was refused. Mr. Raffan suggested the need for keeping constantly in view the retention of those who were engaged in work contributing to the health of the community, and Mr. Long agreed. Mr. Holt expressed the hope that the army would not take even volunteers among medical men and dentists unless they were wanted in connexion with

their own professional duties. There were only too many willing to go and fight, but they would serve their country better at home trying to cure people than by going and killing the enemy. Mr. Long said that it was his intention to make it quite clear that medical men ought not to be allowed to take unnecessary risk unless they could be spared from work which he considered equally important. For the last four or five months he had been endeavouring to impress upon the War Office that it must exercise discretion and care in the demands it made upon the medical men for the war. The proposal to insert the paragraph in the schedule excepting medical men was then negatived without a division.

Standard of Physical Fitness.

In the discussion of the fifth clause of the schedule Captain Amery said that the fluctuations in the standards of rejection for medical fitness had been wide. There was, for instance; a difference of opinion as to teeth. In one place the doctors rejected every man who had more than four teeth missing, while in another it was said that as long as a man was well nourished and had hard gums he might be passed. There were also a few cases of malingering, especially in connexion with alleged defective eyesight. Colonel Yate considered that the number of men rejected as being below the standard of height and measurement might be reduced by a little careful training and extra food. At Leicester 849 men were rejected in 1914; of these 384 had, as a result of competent instruction, been passed as fit, and 254 were still under training, so that of the original 849 only 211 were finally rejected as unfit. Mr. Long admitted that there was some difficulty about the matter. Since the war broke out the work of medical examination had been in some districts indifferently performed, whereas in others the standard set was very high; he instanced the case of one commanding officer who insisted on so high a standard that a great many men were rejected who, now that the medical examination had been more equalized, would be accepted. For this and other reasons he believed that under the existing better organized system a great deal of excellent material would be found among those who were formerly rejected. He believed that the indirect effect of the bill would be to bring in all those who wanted to come in, and as regards the small minority who had got their certificates improperly—and they were the worst kind of shirkers—if there were any other means by which they could be brought in he would not hesitate to ask Parliament to use them. After some further discussion the amendment was withdrawn.

Schools and Colleges.

Another amendment to exempt all men at a school or college, or under articles for the purpose of entrance into a profession was withdrawn, after the Home Secretary had pointed out that the proper course was to allow all such cases to be considered individually on their merits, in accordance with machinery provided by the bill, and had undertaken to introduce an amendment on the report stage. The second schedule setting up local and appeal tribunals, and a central tribunal was adopted with some verbal amendments.

The report stage of the bill was concluded on January 24th, and the bill was read a third time by 383 votes to 36.

War.

Medical Students.—Sir Gilbert Parker, on January 24th, asked what was the policy of the Government with respect to the recruiting of first and second year medical students, and instanced a case in which an applicant had been refused by an officers' training corps on the ground that he was a medical student. Mr. Tennant replied that there had been no change in the policy of recruiting first and second year students, and referred to the answer he had given to Mr. Shirley Benn on January 12th (BRITISH MEDICAL JOURNAL, January 22nd, p. 140), in which he stated that the statistics bearing upon the matter were being further examined. He added that it was not contemplated that qualified medical men should be used as soldiers in the ranks.

Physical Unfitness.—In reply to a question by Sir E. Cornwall, on January 20th, as to whether men otherwise

fit for service who had been rejected on the eyesight test would be afforded another opportunity for examination, with a view to their being utilized in some branch of the service where good eyesight was not of primary importance, Mr. Tennant said that there was nothing to prevent a man who had been rejected in the past as medically unfit on any grounds from presenting himself again if he wished to do so. On the same day Mr. Thomas raised the case of men who, under the Derby recruiting scheme, had only been subjected to a cursory examination and when called up and subjected to a more searching examination were found unfit for service and sent back to civil life. This caused loss and inconvenience to men who were in the position of having to dispose of or wind up a business, or whose positions had in the meantime been refilled, and he asked that measures should be taken to enable men to be finally examined before they severed connexion with their civil occupations. Mr. Tennant promised that every effort should be made to do this.

Artificial Limbs.—On January 20th Sir George Toulmin asked whether the best available artificial limbs were being supplied to officers and men who had lost limbs, and if the whole cost was not paid by the State, what proportion was paid in the case of officers and men respectively. Mr. Tennant said that officers were given such sum as the Army Council considered sufficient to defray the necessary expense of providing the artificial appliances, and the artificial limbs for men were provided and prepared at the public cost. At the institution at Rochampton House all men who had lost limbs could have the artificial limbs fitted under the advice of expert orthopaedic surgeons and receive instruction in the use of the limbs.

Recruits' Eyesight.—Major Lane-Fox on January 19th asked a question as to the rejection of men otherwise suitable on the ground of defects of sight which could be corrected by glasses. Mr. Tennant said that the minimum standard for eyesight for general service was low, and soldiers were given glasses to bring their sight more nearly to the normal. There were, however, cases in which glasses could not bring the sight to a standard sufficient for general service. In reply to a suggestion by Major Lane-Fox, that there was a considerable amount of evasion of military service by men whose eyesight was not really seriously defective, Mr. Tennant said that instructions had for some time been in force to the effect that a mere statement of inadequacy of vision was not to be regarded as sufficient reason for excusing military service.

Insanity of Wives.—On January 20th Mr. Samuel asked a question as to the case of a soldier now serving in France whose wife had lost her reason and had to be temporarily taken to an asylum and his two children to the cottage home of the guardians. He asked whether by this not only was the soldier disfranchised, but also the army allowance for the maintenance of his wife and children stopped. Mr. Long said, in reply, that under the Electoral Disabilities (Naval and Military Service) Removal Act, 1914, the soldier would not be disfranchised on account of the circumstances mentioned, nor would the issue of an army allowance in respect of the maintenance of the children be discontinued, but, as the War Office Order stood at present, it did not refer to wives' allowances. He believed, however, that the matter was under consideration. In reply to a further question, on January 24th, Mr. Forster said that the separation allowance issued in such a case was at the higher rate given when children were motherless.

Lunacy Institutions.—In reply to Mr. Shirley Benn, Mr. Tennant stated, on January 20th, that the lunacy institutions being used in whole or in part for the accommodation of unwounded soldiers invalided through transient loss of balance or mental disorder were: Springfield War Hospital, Wandsworth; the Napsbury War Hospital, St. Albans; the Red Cross Military Hospital, Maghull, near Liverpool; and the War Hospital, Peebles, N.B. The institutions had been taken over by the War Office, and were entirely under its control.

Wastage.—Colonel M'Calmont asked, on January 24th, what proportion of the 15 per cent. calculated as the average monthly wastage for infantry of the expeditionary forces must be reckoned as permanently non-effective, and what proportion must be considered as requiring replacement by drafts from home. Mr. Tennant said that the matter could not be conveniently dealt with in an answer to a question, and he doubted whether it could be

discussed in public without giving to the enemy information better withheld.

The Statistics of Enteric Fever in the British Armies.—Mr. W. Thorne asked the Under Secretary of State for War, on January 20th, why no statistics were given of the balance of 215 cases of enteric fever over and above those diagnosed after bacteriological examination; if cases bearing the name of para-typhoid fever, trench fever, pyrexia, and other pseudonyms of enteric fever were included in the totals furnished by him; and, if not so included, would he furnish statistics of cases and deaths diagnosed under those heads, as well as those for the 215 cases of enteric fever referred to above? Mr. Tennant said: The 215 cases consisted of those waiting bacteriological examination and also of some cases which, in the early days of the war, were not bacteriologically examined, but were diagnosed as enteric fever on clinical grounds only. The diseases mentioned in the second part of the question were not included in figures I gave on January 10th. I cannot accept my hon. friend's suggestion that those diseases are pseudonyms for enteric fever. No statistics are available of the cases of trench fever and pyrexia. My hon. friend's question appears to me to suggest, though, no doubt, inadvertently, that the medical authorities hide cases of enteric fever by falsely returning them under other names. So far as this suggestion is contained in the question, I must repudiate it. I did not give particulars of the cases of para-typhoid in my answer of January 10th because no system of inoculation for that disease has been adopted.

Vaccination.—On January 25th Mr. Tennant informed Mr. King that a soldier deemed to have enlisted under the Military Service (No. 2) Bill would not be deemed to have consented to be vaccinated.

Direction of Army Medical Services.—Mr. Lynch, on January 20th, asked whether, as the Army Medical Services were subjected to dual control, one Director-General being in England and another in France, who might work contrary to the plans of the Director-General in England, and who possessed authority to upset the units of hospitals as soon as they arrived in France, appropriate steps would be taken to deal with the matter. Mr. Tennant replied that the appropriate steps for dealing with the matter would be to make no change. There was no conflict of authority. Medical units in the field were under the orders of the Commander-in-Chief to dispose of in any way that was thought fit, and he did not see how it could be otherwise.

Salaries of Director-Generals.—Mr. Lynch, on January 20th, asked what was the total of the emoluments at present being received by the Director-General in England, including present pay plus pension and salary as President of the Imperial College of Science and Technology; what emoluments were being received by the Director-General in France; and whether he was receiving the salary of a Director-General, together with allowances, as well as a wound pension. Mr. Forster: The Director-General of Army Medical Services at the War Office is receiving from army funds £2,000 a year pay and £625 pension. He is receiving nothing from the Imperial College of Science and Technology. The Director-General of Medical Services in France is receiving £2,000 a year pay and the field allowance of his rank (£273). His wound pension was commuted some years ago.

Remuneration of Re-employed Retired Officers, R.A.M.C.—Mr. Lynch, on January 20th, asked whether retired officers, R.A.M.C., who had been called up for active service were now receiving full pay of rank in addition to full pension, and what pay was each surgeon-general and each colonel receiving. The Financial Secretary to the War Office (Mr. Forster) said that the answer was in the affirmative except in the case of a small number of surgeon-generals who had given their services in posts of a grading not commensurate with their rank, who drew £600 a year in addition to pension.

R.A.M.C. Income Tax.—On January 25th Mr. Watt asked whether according to the pay of officers of the R.A.M.C. sent in December there was a notice saying that income tax would in future be deducted at the rate of 1s. 9d. in the £, and whether this notice was in conflict with the Chancellor of the Exchequer's statement that these incomes would be subject only to a reduction of 1s. 6d. in the £, even though the general tax was raised to a higher level. The Financial Secretary to the Treasury said that

he understood that no general notice of the nature indicated had been issued to officers of the R.A.M.C., but he pointed out that under the Finance (No. 2) Act, 1915, the proper rate of deduction from the pay of officers whose total income exceeded £300 and did not exceed £1,000 was for the year ending April 5th next 1s. 9d. in the £.

Promotion in R.A.M.C.—Mr. Laurence Hardy, on January 25th, asked the Under Secretary of State for War whether temporary lieutenants of the R.A.M.C. and captains received considerably higher pay than captains, Special Reserve R.A.M.C., although in many cases the latter officers served before the war, whilst the former had no previous experience; whether there had been no promotion in the Special Reserve R.A.M.C. since the war beyond the rank of captain, though there were now in the service 543 captains of the Special Reserve as against 39 at the outbreak of war; and whether he could see his way to giving equal pay and opportunities for promotion to this branch of the R.A.M.C. as were enjoyed by the other branches of the medical services, namely, Regulars, Territorials, and temporarily enlisted. The Financial Secretary to the War Office made a written reply as follows: Captains R.A.M.C. Special Reserve receive the same pay as captains R.A.M.C. Regular Army. Their emoluments are nearly the same as those of temporary lieutenants or captains serving under civil contract. The large number of captains in the Special Reserve is due to recent promotions, and can hardly be made a reason for further promotions. The senior captain in the Special Reserve has less service than the senior captain in the Regulars. It does not appear that officers of the Special Reserve are at a disadvantage.

British Prisoners in Turkey.—Mr. Tennant, on January 24th, stated, in reply to a question by Mr. Macmaster, that the number of officers and men of the Royal Navy and the British regular, colonial, and Indian forces at present prisoners in Turkey were as follows: Officers 47, other ratings and non-commissioned officers and men, 598. Although letters from individuals not infrequently spoke of markedly good treatment, there was reason to fear that the general condition of internment in Turkey was far from satisfactory; but, owing to the remoteness of some of the camps and the difficulties of communication, it was hard to ascertain the actual state of affairs. The American Ambassador at Constantinople had done everything in his power, but had been unable to obtain the consent of the Turkish Government to visit the internment camps.

German Army Casualties.—Mr. Tennant, on January 19th, gave the following as the casualties for the whole German army, founded on the best information available, and coming down, he believed, to the end of the year:

Killed	588,986
Died	24,080
* Wounded	1,566,549
Missing and prisoners	356,153
Total	2,535,768

* This figure includes both wounded and severely wounded.

In reply to a further question, Mr. Tennant said that the information at his disposal was not by any means complete.

[The figures given by Mr. Tennant on December 21st, 1915, will be found at p. 26 of the JOURNAL of January 1st, 1916. The total then given was to November 30th, 1916, and was about 11,000 lower than in the above table. The total now returned as killed is, however, over 100,000 higher.]

Local Loans.—The President of the Local Government Board has stated that since the outbreak of the war it has sanctioned 997 loans to local authorities, amounting in the aggregate to £12,647,187. Of this amount £8,929,560 was sanctioned prior to March 26th, 1915.

THE book entitled *Makers of Man: A Study of Human Initiative*, by Dr. C. J. Whitby of Bath (Rebman, 1910), has been translated into Japanese by a society organized in Tokyo in 1908 under the auspices of Count Shigenobu Okuma, the well-known statesman and educationalist, to popularize Western information and ideas. The "Dai Nippon Bummel Kyokwai," whose objects are comparable to those of our University Extension Movement, has already issued translations of about a hundred standard works of various nationalities chosen by its committee.

THE WAR.

ARRANGEMENTS FOR CONVALESCENT OFFICERS.

(From a Correspondent in Northern France.)

THE existing arrangements for the benefit of officers convalescent from wounds received or disease contracted on active service during the war, are much the same as those which proved so useful last winter. Superficially, indeed, they are identical, except for the fact that the institution closed at Ciniez last May and reopened in November has had included in its title the name of the lady who furnishes the British Red Cross Society with the funds for its maintenance. It is known, therefore, as the Michelham Convalescent Home for British Officers. A more important difference is that the home is classed this year as a military hospital, and that consequently the regulations in regard to its administration and the admission of patients are somewhat more stringent.

The officers regarded as having the first claim on the accommodation from time to time available are those suffering from the effects of wounds or whose ill health is due to the especially trying conditions of life within the fighting zone. Other officers—namely, those serving at the bases or on the lines of communication—are also eligible for admission, but in their case the regulations seem to anticipate that before their names are submitted for the approval of the D.G.M.S. they will be sent before an ordinary medical board. Cases of a chronic kind, such as neurasthenia and phthisis, as also patients who can be classified as mental and severe surgical cases, are definitely excluded.

There is room for one hundred patients, and as vacancies occur they are usually sent down in batches. At Paris they are met by an official of the Paris branch of the British Red Cross Society, and if necessary are visited by one of its medical officers. The society also arranges to send down a nurse or orderly with any officer who is unfit to travel unassisted. The medical officer, or medical board certifying as to the nature of a case, must state the duration of stay recommended, which must not exceed thirty days. If eventually a longer period prove very desirable, responsibility for its extension rests with the medical officer in charge of the home. The patients on their discharge are sent, as a rule, to the base details dépôt of their unit, where they are re-examined by a medical board before rejoining their battalions; some, however, are allowed to take up their work forthwith if this be of an administrative order, and the commanding officer of the home considers them fit for it.

The commanding officer, who has the title of Commandant, is a Lieutenant-Colonel, R.A.M.C., and has two officers of the same corps to assist him. The matron is drawn from Queen Alexandra's Imperial Military Nursing Service, but the nurses and the rest of the personnel belong to the Red Cross.

Each officer in residence has a bedroom to himself, but meals are taken in common. The wearing of uniform is compulsory, except during the playing of games in the park attached to the hotel in which the home is situated. In order to encourage the patients to keep in the open air as much as possible, no card games are allowed to be played before 4 p.m. If, however, the weather is very inclement the commanding officer can relax this rule. There are also regulations as to the hours between which officers can absent themselves from the home, and as to the hour at which all lights must be out.

The general idea of these arrangements is to ensure maintenance of the right military tone despite the influence of past illness, of freedom from duty, of an environment not essentially dissimilar from that of a large Riviera hotel, and of the proximity of friends and relations, for arrangements have been made by which a certain number of the latter can find accommodation on low terms at hotels in Nice, and they can be invited to luncheon and tea at the home. The special value of this home, from a military point of view, is that, besides affording officers a chance of getting fit for duty earlier than would be likely to be the case if they had to recruit their strength in a less genial climate than that of the

Côte d'Azur, it obviates in a great many cases the necessity of granting them sick leave. To this step there are held to be distinct military objections when war is in progress, and when the officers concerned are not suffering from wounds or sickness likely, in the ordinary course of events, to incapacitate them for an indefinite time.

A home of similar purpose, but somewhat less formally administered, has been at work at Dieppe for a good many months for officers belonging to the Canadian contingent, and one for the use of Red Cross nurses and members of Voluntary Aid Detachments employed with the army was opened in Mentone in November. There is no corresponding place for army Sisters, but, on the other hand, a rest home, at which nurses who have been ill or are more or less "run down" can obtain a change of scene and surroundings, has been at work at Hardelet for nearly a year, and I believe there is another at Rouen. The ladies to whom these homes owe their existence, and by whom they are conducted, have official sanction for their work, and they have undoubtedly been of the greatest utility.

Those specially interested in the Ciniez home will find a more detailed account of its arrangements, and some of the considerations attaching to the maintenance and management of such institutions, in the BRITISH MEDICAL JOURNAL for April 3rd, 1915. It was then known as Queen Mary's Convalescent Home for British Officers.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

THE casualty list published on January 22nd gives the name of Lieutenant J. Le K. Mavety, R.A.M.C. (temporary), as having died in France. He was attached to the Royal Field Artillery. He joined the R.A.M.C. from the Canadian Army Medical Corps in June last.

Wounded.

Captain H. S. Milne, R.A.M.C., Special Reserve, France.
Lieutenant R. E. Thomas, R.A.M.C. (temporary), France.

DEATHS AMONG SONS OF MEDICAL MEN.

Gwynne, Owen Perrott, Second Lieutenant, 92nd Punjabis, younger son of the late Charles N. Gwynne, M.D., of Sheffield, killed in Mesopotamia, January 6th to 8th, aged 25. He was born at Sheffield, educated at Loretto, and was for five years an engineering pupil with Vickers, Maxim, and Co. He then went to Ceylon as resident engineer on the Dunsinane tea gardens. When war broke out he joined the Ceylon Planters' Corps, with which he went to Egypt. He then got a commission in the 92nd Punjabis, took part in the battle of Irmak, and accompanied his regiment to Mesopotamia. His only brother, Captain J. F. Gwynne, R.A.M.C., fell at Ypres on July 9th, 1915.

Macnaught, Frederick Clement, B.Sc. Lond., Lieutenant R.E., elder son of the late Frederick Macnaught, L.R.C.P. and S.Ir., of Walsham-le-Willows and of Bow, London, killed at Loos on September 25th. He obtained his commission on September 24th, 1914, and was attached to the 1st Field Company of the 24th Division, R.E.

Mouillot, Augustus de Thierry, Captain 51st Sikhs, only son of the late Dr. Mouillot, of Harrogate, died in Mesopotamia, on January 12th, of wounds received January 6th to 8th, aged 33. He was born on June 21st, 1882, got a commission through the militia as Second Lieutenant in the Bedford Regiment on July 4th, 1903, entered the Indian army and was posted to the 51st Sikhs on October 1st, 1906, and became Captain on April 8th, 1912. He served in the South African war, and afterwards at St. Helena, receiving the Queen's Medal with three clasps.

Wylie, Hamilton MacLaren, Second Lieutenant 1st Battalion Seaforth Highlanders, youngest son of the late Dr. James Hamilton, inspector of schools, killed in Mesopotamia on January 7th, aged 22. He was educated at Repton and at Pembroke College, Cambridge, joined the London Scottish in September, 1914, went to France with the first draft to that regiment, and got a commission in the Seaforths in August, 1915.

NOTES.

HONOURS.

ON January 21st the Admiralty published a list of honours bestowed on naval officers for services in the Persian Gulf and Mesopotamia. Among them Surgeon Dermot Loughlin, M.B., R.N., receives the Distinguished Service Cross for attending the wounded under a heavy fire at close quarters on board the *Comet* on the night of September 28th, 1915.

A list was issued at the same time of officers and men mentioned for their services with the British Naval Mission

to Serbia. Among those mentioned is temporary Surgeon E. R. A. Merewether, R.N.

The *London Gazette* of January 22nd announces the award of a large number of honours to officers and men for distinguished service, four Victoria Crosses, seven D.S.O.'s, 35 Military Crosses, and 179 Distinguished Conduct Medals. One medical officer, Captain A. Findlater, R.A.M.C.(T.F.), gets the D.S.O., and one, temporary Lieutenant J. W. Gilbert, the Military Cross.

D.S.O.

Captain Alexander Findlater, M.D., 1st London Mounted Brigade Field Ambulance, R.A.M.C.(T.F.). For conspicuous gallantry and devotion to duty on several occasions, notably on September 29th, 1915, at Chocolate Hill, Gallipoli Peninsula. He crossed over two hundred yards of open ground under very heavy shell fire to render aid to two wounded men. He saved the life of one, but the other was beyond help.

Military Cross.

Temporary Lieutenant John Wesley Gilbert, R.A.M.C. (attached 9th Brigade, R.G.A.). For conspicuous gallantry and devotion to duty near Ypres on December 29th, 1915. After three attempts he succeeded in entering a farm, which was being heavily shelled with gas and other shells, and rendered valuable help to the wounded infantry who were billeted there.

We are informed that Captain M. A. Macdonald, R.A.M.C., M.B.Glasg., has been recommended for the French Military Cross for services under fire at Gallipoli.

Captain William Albert Colhoun, of the 4th Battalion Royal Irish Fusiliers, who received the Military Cross in the list of honours gazetted on January 14th, is a fourth-year medical student of Trinity College, Dublin.

MEDICAL OFFICERS WANTED.

2nd London Sanitary Company.

Medical men required as sanitary officers, each to command a sanitary section of 25 n.c.o.'s and men; every probability of going overseas at an early date. Those engaged in public health work and possessing the D.P.H. preferred. Applications to Captain F. G. Caley, R.A.M.C.(T.), Officer Commanding, Duke of York's Head Quarters, Chelsea.

2/1st Eastern Mounted Brigade Field Ambulance.

Medical officers required for this ambulance. Pay as in regular army. Foreign service obligation necessary. Applications to the Officer Commanding, Hurst Park, London.

3/2nd East Anglian Field Ambulance.

Medical officer urgently required. Pay and allowances as in regular army, also an outfit and field kit allowance. Applications to Officer Commanding, Halton Park, Tring.

Sydney.

SOLDIERS AND ALCOHOLISM.

A MEDICAL committee was appointed some time ago to report on the health and sanitation generally of the camp at Liverpool. The committee consisted of the Principal Medical Officer of the Second Military District (Colonel Perkins); Professor Welsh, Professor of Pathology in the University of Sydney, and Drs. Paton, W. G. Armstrong, and Cleland, of the Board of Health. The report states that the conditions of camp life at Liverpool revealed certain predisposing causes of disease. Some of these, which were incidental to the training of the soldiers, included exhaustion and fatigue, associated at one time with overheating and saturation of the clothing with perspiration, and at another with cold and wet. Such conditions depressed vitality and predisposed to disease. With reasonable care, however, such depressant effects might be mitigated. Other influences, however, were at work which were much more potent in lowering the resistance to disease. The two outstanding of these influences were intoxication by alcohol and defective ventilation and overcrowding. There was evidence that alcoholism was prevalent and excessive among the recruits. If drunkenness were checked, the committee was convinced that venereal disease would be much less common, and the susceptibility to other infectious diseases would be diminished. There was no other single cause which had so profound an effect on the health and efficiency of the troops. The committee, therefore, recommended that the following regulation should be introduced to minimize the opportunities of alcoholic excess: (1) Wet canteens should be established for the sale of light ales and wines

served with ice, at moderate prices. They should be under official control, and the profits might go towards improving the canteens and the camp. The site should be preferably within the camp, or, if that be not practicable, it should be close outside. At Liverpool it should be on the same side of the river as the camp. (2) The town of Liverpool and district west of the railway line should be put out of bounds in order to eliminate the public-houses and the women of ill repute. (3) All public-houses throughout the state, except authorized canteens, should be closed to soldiers in uniform after 6 p.m. (4) Shouting for soldiers in uniform should be made illegal, as it is for all persons in proclaimed munition areas in England. (5) Discrimination should be exercised in granting leave. No late leave should be given except for special purposes or to reliable men. Ordinary leave should require return to camp before dark. Drunkenness should be penalized by curtailment of leave. (6) Ladies' club; might be formed for the purpose of entertaining men on leave, especially those from the country, in circumstances that would encourage their self-respect.

Further efforts have been made with a view to diminishing the evil effects of drink among the soldiers. The district commandant states that conferences have been held between representatives of the military authorities and the executive of the Licensed Victuallers' Association with the object of preventing the misuse of intoxicating liquors by soldiers on licensed premises. It is stated that in some places publicans have found that when they have endeavoured, in the interests of the young men concerned, to give them friendly advice as to restraint in the use of liquor, and have endeavoured to prevent them obtaining more than was good for them, some of the general public have interfered on behalf of the soldier, and resented the advice of the publican. With a view to establishing in the minds of all the fact that over-indulgence in intoxicating liquor is an offence, and that the presence of intoxicated men on licensed premises is also an offence, a notice has been posted in the bars of hotels setting out the fact that soldiers in uniform under the influence of liquor must not enter or remain upon licensed premises; and that the licensed victualler must not suffer any soldier under the influence of liquor to enter or remain upon his premises. It has been further pointed out that under the War Precautions Act persons who take part in any action calculated to be subversive of discipline, or to prejudice the good conduct of a soldier, are liable to heavy penalties.

GERMAN DRUGS.

A deputation, consisting of Mr. Bailey, President of the Australasian Pharmaceutical Conference; Mr. Buckhurst, President of the Federal Pharmaceutical Council; Mr. R. Grimwade (Felton, Grimwade, and Co.); Dr. Sidney Plowman, Lecturer on Materia Medica and Pharmacy at the College of Pharmacy; and Mr. D. Rankin, Past-President of the Pharmaceutical Society, waited on Mr. Hughes, the Prime Minister, recently and asked him to cancel the aspirin licence and prevent German trade marks being used. In reply, Mr. Hughes promised carefully to investigate the question of striking off the trade marks register all German trade names, and that the Government would do all that was possible to encourage the manufacture in Australia of raw materials for drugs that previously came from Germany. He also promised an inquiry into an allegation that German drugs were reaching Australia through neutral countries. He had no prejudice in favour of retaining the word aspirin; the whole matter was receiving attention as part of a general policy to deregister all German trade names. He thought there was no doubt, under the Enemy Trade Marks Act or the War Precautions Act, that the Commonwealth had the power to do anything within reason in the protection of the country.

During the interview it was stated that since the renewed activity of British submarines in the Baltic the price of certain drugs in Australia had gone up by leaps and bounds. Referring to this statement, Mr. Hughes said that if it were true it was a startling fact, and he did not know whether the deduction that enemy drugs were getting into Australia through neutral countries was not justified. He asked for a list of these drugs which had shown these extraordinary and significant variations in prices.

NEW PRINCIPAL MEDICAL OFFICER FOR THE NEW SOUTH WALES MILITARY DISTRICT.

Last month the Minister for Defence decided that the appointments of Principal Medical Officer in the second and third military districts were of sufficient importance during the continuance of the war to necessitate the service of an officer who could devote his whole time to the duties. Hitherto the pay for these appointments had not been commensurate with the duties and responsibilities of a capable officer so employed. The occupants of the "part-time" positions were consequently required to vacate their positions on November 30th, 1915, and applications were called from the medical profession, either with or without military experience, to fill the vacancies at £800 per annum. The selection was to be made of the most suitable applicant of the highest professional attainments, who must be a capable organizer and administrator, irrespective of rank. The appointment was to be for a period of six months on probation, to be confirmed if satisfactory for the period of the war and four months afterwards, the successful applicant to be granted the temporary rank of colonel in the Australian Army Medical Corps while holding the appointment. The applications were referred to a committee consisting of the Adjutant-General, the Director-General of Medical Services, the commandant of the district concerned, and the President of the Branch of the British Medical Association of the district concerned. This Committee submitted their recommendations to the Minister, and Lieutenant-Colonel E. S. Stokes was appointed for New South Wales.

Lieutenant-Colonel Stokes has been for the past ten years medical officer to the Water and Sewerage Board. He is 47 years of age, possesses organizing ability, and in addition has seen service in the present war. He left Sydney with the rank of Major in the First Field Ambulance, and after spending some time in Egypt joined the staff of Brigadier-General MacLagan, who was in command of the Third Brigade and detached forces. He then proceeded to Lemnos, and on April 25th landed with the 2nd Field Company of Engineers in connexion with the water supply. Shortly after landing he was appointed Deputy Assistant Director of Medical Services to the First Australian Division, under Colonel Howse, V.C., C.B., with the rank of Lieutenant-Colonel. Among other duties he had to take charge of the sanitary arrangements of the area occupied by the First Infantry Division. Subsequently he became ill, and was given leave to return to Australia. His leave had almost expired, and instead of returning to the front he has taken up the duties of his new position.

Canada.

THE CANADIAN MILITARY HOSPITAL COMMISSION.

The Military Hospital Commission meets once a month, but subcommittees have been formed in each province, consisting of the representatives of that province on the Commission, to make arrangements for the accommodation and medical treatment of invalided members of the Canadian Expeditionary Force. It is estimated that only about 10 per cent. of the men who return to Canada require further hospital treatment on their arrival. Ample accommodation in convalescent homes has been provided throughout the country, and any invalided soldier who returns to Canada, and who has not been discharged from service, can be placed in one of them on making application to the Secretary of the Hospital Commission at Ottawa. Arrangements have been made with the Red Cross, the Daughters of the Empire, and other societies for the provision of comforts in the shape of clothing, books, and papers. Convalescent homes have been established at Sydney, St. John, Montreal, Toronto, Hamilton, London, Calgary, Victoria, among other places, and in each arrangements have been made for electrical treatment, massage, and other remedial measures in cases of atrophied limbs and stiffened joints. Soldiers suffering from tuberculosis are sent to a sanatorium, and 10 dollars a week is paid by the Government for their treatment. The men are kept in the convalescent homes as long as there is reasonable hope of improvement, but when this exists no longer they are discharged on a pension. These

men have all been examined and classified in Great Britain prior to embarkation. On arrival in Canada they are sent to the clearing hospital at the port of debarkation, where they undergo a further examination, and, if necessary, they are sent to hospital or to one of the convalescent homes. If discharged, they are given a pension and three months' pay, payable in three monthly instalments. A careful record of all cases is kept, including the nature of the disability, the occupation prior to enlistment, the possible sources of income, and the nature of the occupation they would like to follow if unable to continue the work in which they were engaged before enlistment.

The provision of employment for such men has been undertaken by provincial committees, to each of which a representative of the Hospital Commission has been appointed. This branch of the work was formerly in the hands of the Patriotic Fund.

Ireland.

WORKHOUSE AMALGAMATION.

At the last meeting of the Cork County Council, the chief business was to consider generally the question of the amalgamation of the Poor Law Unions of the county and other matters connected therewith. The following resolution was unanimously adopted:

That having regard to (1) the great decrease in the population since the present Unions were established; (2) the fact that there is no unemployment at present existing; (3) that the sum of £190,000 approximately is paid yearly throughout the county under the Old Age Pensions Act; (4) that a sum of £15,000 approximately is paid to insured persons in the county under the National Health Insurance Act; (5) the greater possibilities afforded by railways and motor ambulances, we consider that several workhouses could with advantage be abolished, and the Unions amalgamated with adjoining Unions; and that the Local Government Board be asked to hold an inquiry at the County Courthouse, Cork, at which the guardians of the several Unions and other persons interested may be represented.

A DOCTOR'S SUPERANNUATION.

At its last weekly meeting the Enniscorthy Board of Guardians rescinded a resolution passed in November last, granting their late medical officer, Dr. Thomas J. Kelly, a superannuation allowance of £100 a year. The guardian who moved the rescinding resolution (which was carried by a vote of twenty-one to fifteen) said that when they were kind and generous enough to give Dr. Kelly £100 a year he at once wrote off to the Local Government Board, and complained that certain emoluments had not been taken into consideration. As the clerk had since informed them, the doctor's statement was incorrect. It was to punish the doctor for writing such a letter, and to show him and all officials that the dignity of the board of guardians must be respected that he moved his motion. Several proposals were then put forward as to the amount which should be granted the doctor. The sums ranged from £100 to £20. The final vote was between £75 and £50, and the latter sum was carried by twenty-two votes against fifteen.

RED CROSS FUND.

From the reports of the local committees presented to a meeting of the central committee of the Leitrim Red Cross Fund last week it appeared that, although this fund was only started in November last, the substantial sum of nearly £900 had been collected. It was decided to allocate the fund as follows: £470 for the purchase, through the War Office, of a Sunbeam motor ambulance, bearing the inscription "Presented by the County Leitrim for service with the 10th (Irish) Division of the British army in the field"; £300 to the British Red Cross Society, and the balance to the Connaught Rangers' Comforts Fund, including prisoners of war. It was decided to keep the fund open for further subscriptions until January 31st, 1916.

THE *American Journal of Orthopedic Surgery* will in future be published at Boston and will appear monthly instead of quarterly. While continuing to be the official organ of the American Orthopedic Association, its scope will be enlarged so as to appeal to surgeons and general practitioners as well as to specialists.

Correspondence.

THE SOLDIER'S HEART AND THE STRAINED HEART.

SIR,—One may well be glad and satisfied with the recent discussion anent the soldier's heart at the Royal Society of Medicine, for it gives expression to an opinion from those well qualified to give it, that "the soldier's heart" is but our old enemy "the strained heart" now come out into the open, and sailing under its true colours. It is much to be hoped that this will sink home into general practice: that the so-called "strained heart" is not a muscular fault, but a temporary overdraft of current account of nervous energy, and that we shall hereafter—vain hope, I fear—banish that vicious term from our nosology, shrouding as it has done, and does, so many young men and women, and even children, in its winding sheet of "dilatation of the heart" for months, nay, often for years, when they should never have been invalidated in that sense at all.—I am, etc.,

London, W., Jan. 22nd.

JAMES F. GOODHART.

SIR,—My remarks on the "Soldier's Heart" in the discussion on that subject (JOURNAL, January 22nd, p. 131) were quite extempore, and I had hoped that the larger question of the heart in the soldier might have been considered. Consequently your report, which is necessarily brief, makes me rather too emphatic as to the hopelessness of the future of such a condition in the soldier. Recovery depends a good deal on the man himself. The term, the "soldier's heart," like any other which may be defined, might be allowed currency, as also might that of the "soldier's brain" or the "soldier's spinal cord." But it is, I think, of questionable utility that one of many evidences of shock and exhaustion should be emphasized to the exclusion of the general state in which it is merely an incident. This tendency to the specialization of effect, in the case of an agent acting generally, is rather amusingly evident at present in that capture from secretions and excretions of organisms regarded as having a particular effect upon a given organ.

Excluding possibilities of contamination—frequently a difficult matter—by such care as the bacteriologist can exercise, what reason is there to suppose that the organism (or its assumed toxins) which he captures from the excretions or secretions are the actual cause of a local condition, the blood itself not growing any such organism, and the host showing no morbid reaction to the invasion? There is admittedly no proof, and however fruitful the suggestion may prove, it can at present be regarded as no more than a suggestion, and that unsubstantiated. As a matter of fact, the soldier's heart is but an incident in a general neurasthenia or state of exhaustion, and exemplifies the relation of the nervous system to sustained energy in the viscera.

The detachment with which some, of recent years, have been wont to regard cardiac motion, has placed rather in the background the relation of cardiac energy to the nervous system, but some modification of this attitude has been the result of a better knowledge of the relation of the excitatory structures in the heart to it.

Dr. Poynton referred to cases in which the general and particular collapse of the patient had apparently been a direct result of high explosive agency, and most of those who have had to deal with such cases, in the course of the present war, must be in a position to recall instances of this relation between apparent cause and effect. The immediate cardiac effect in such cases is probably a profound inhibition, for the patient usually gives a history of a temporary state of unconsciousness immediately consequent upon undergoing this experience.

Many, perhaps most cases, however, are the result of a general exhaustion without direct relation to high explosive agency. Indeed, the "soldier's heart" may occasionally be met with in the overworked civilian, harassed by anxiety, and, as distinguished from particular disorders of the heart induced by the life of the soldier, it is but an incident in the generally shattered nerve energy of the patient, who is, in short, a neurasthenic with exaggerated sensibility. One sees, for example, seasoned soldiers of fine physique suffering from so general an exaggeration of

sensibility, as to conceal altogether the local cardiac condition, with sighing respiration and inability for exertion. In this general state, no evidence of local lesion in the nervous system may be notable, beyond the marked psychasthenia and neurasthenia of which the exaggerated sensibility is an expression. Such a condition might as well, as I have said, be termed the "soldier's brain" or "spinal cord," as the cardiac state the "soldier's heart." Nevertheless, given a definition, we recognize the condition.

The treatment, therefore, of the "soldier's heart" is the treatment of a general neurasthenia which is a grave disorder and by no means hysteria. It should consist in the first place of general and absolute rest, followed on a degree of recuperation, by gradually increasing physical exertion and mental change.

The creation or acquisition of psychical rest is the most important element in the successful treatment of such cases, for it brings with it refreshing sleep. The removal of the apprehension of breakdown may in time lead to the reconstitution of the power of endeavour—the recovery of endurance. Those who attain this, however, are usually men of some mental force, who accept their measure of disability and face its consequences with the same resolution and indifference to death, if necessary, in the discharge of their duty with which, in more perfect health, they face death in the actual shock of combat. The neurasthenic who becomes introspective and critical of his state is lost. For this reason, while in general agreement with the opener of the debate on the soldier's heart in his views of its treatment, I question whether good would result from the collection of such cases in a sanatorium specially devoted to their care. The companionship of a man who had lost his leg would be more conducive to his recovery than that of a fellow sufferer from neurasthenia with or without subjective cardiac distress.—I am, etc.,

London, W., Jan. 22nd.

ALEXANDER MORISON.

SIR,—It would have been interesting and helpful had the discussion on the soldier's heart at the Royal Society of Medicine on January 18th dealt with the relation between excessive cigarette smoking and "irritable heart." Several soldiers have told me that it is quite common to smoke thirty or forty cigarettes a day, and even more than that at times. No one will deny that this is an excessive number, and that the absorption of a powerful poison like nicotine does adversely affect the heart in spite of a certain tolerance acquired by use. Excessive tobacco smoking may be a more important factor in the production of "soldier's heart" than is imagined.—I am, etc.,

Warrington, Jan. 24th.

J. S. MANSON.

STRANGE WOUNDS CAUSED BY HIGH EXPLOSIVES.

SIR,—In view of Dr. J. Lewis Thomas's opinion that the strange wounds caused by high explosives are "due to the escape of internal body pressure into the vacuum produced by the explosion," the following fact which came under my own observation may prove of interest:

One night in a small town in Flanders in which I was billeted at the time several bombs were dropped. One exploded in a field, making a hole about 15 ft. in diameter. The explosion was a few yards away from the end of a barn, which was built of bricks. The curious thing about it was that this end wall instead of being blown in had fallen outwards flat, with the bricks still in position, the rest of the barn being intact. Evidently this must have been due to the vacuum caused by the explosion, and not by the explosion itself.—I am, etc.,

J. H. HOBLING, Major R.A.M.C.T.

Weston-super-Mare, Jan. 17th.

THE BACTERIA OF GANGRENOUS WOUNDS.

SIR,—Major H. R. Dean and Captain T. B. Mount in their article on the bacteria of gangrenous wounds (BRITISH MEDICAL JOURNAL, January 15th, p. 77) refer to one type of bacillus which they isolated as *B. oedematis maligni*. Their account of this organism, however, seems to point rather to its being *B. cadaveris sporogenes* or some closely allied saprophyte. The absence of pathogenicity supports this view. There is undoubtedly a large group of bacilli,

morphologically identical, which are of faecal origin, and frequently swarm in lacerated wounds. This group is somewhat fully discussed in the late Dr. v. Hibler's monograph *Ueber die pathogen. Anaëroben*. In the autumn of 1914 I was privileged to work on this subject with Lieutenant-Colonel L. W. Harrison, D.S.O., and isolated a number of strains. Several, which were pathogenic to the guinea-pig, conformed most closely to "Art. XI" of v. Hibler, while the majority of the remainder, presenting cultural characters similar to those described by Major Dean and Captain Mouat, conformed to the account of *B. cadaveris sporogenes*. All the bacilli of this group are flagellated and actively motile (even the sporing forms) while *B. aërogenes capsulatus* is non-motile and devoid of flagella.

As I have no books with me I am unable to give more exact references.—I am, etc.,

J. F. SMITH,
Captain, R.A.M.C.(temp.)

France, Jan. 19th.

Public Health

AND

POOR LAW MEDICAL SERVICES.

VITAL STATISTICS IN ENGLAND AND WALES, 1915. WE are indebted to the Registrar-General for the following statement showing the birth-rates and death-rates and the rate of infantile mortality in England and Wales and in certain parts of the country during the year 1915.

ENGLAND AND WALES.

Birth-rate, Death-rate, and Infant Mortality during the Year 1915 (Provisional Figures).

	Annual Rate per 1,000 Living.*			Deaths under One Year per 1,000 Births.
	Births.	Deaths.		
		Crude.	Standardized.†	
England and Wales...	21.9	15.1	14.8	110
95 great towns, including London	22.8	15.6	15.9	117
148 smaller towns...	21.6	14.0	14.2	114
England and Wales, less the 244 towns	20.7	14.8	13.6	98
London	22.6	16.1	16.1	112

* Populations in the middle of 1914, estimated by the method described in the Registrar-General's Annual Report for 1907, have been used in the calculation of these rates, no reliable estimates of population in the middle of 1915 being available.

† The standardized death-rates are the rates which would have been recorded had the sex- and age-constitution of the populations of the several areas been identical with that of the population of England and Wales as enumerated in 1901. A description of the method of standardizing these death-rates will be found in the Annual Report for 1911, page xxix.

POOR LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

At a meeting of the Council of the Poor Law Medical Officers' Association on January 20th among other questions considered was that of the increased cost of drugs used in Poor Law practices. The Honorary Secretary, Dr. Major Greenwood, said that in 1864 a Committee of the House of Commons recommended that "in future cod-liver oil and other expensive medicines should be provided at the expense of the guardians," and in consequence a circular, dated April 12th, 1865, was issued by the Local Government Board ordering boards of guardians to carry out this recommendation. It was, perhaps, stretching the order too much to say that under it the guardians were compelled to pay for drugs that had become expensive medicines owing to the war, but in all equity the guardians ought to meet such increases by increasing the salary or making a special grant, and many boards had done so.

The Honorary Secretary reported that, in reply to a letter from a member, he had expressed the opinion that a joint appointment as district medical officer and workhouse medical officer at an inclusive salary was illegal. The two offices were treated in the Poor Law Orders as separate. The Council agreed, and expressed the opinion that representations should be made to the Local Government Board on the subject at the first opportunity.

With regard to the question of the federation of Poor Law sectional associations, the Council expressed the opinion that the matter ought to be deferred until after the war.

Medico-Legal.

ALLEGED IMPROPER USE OF THE TITLE OF DOCTOR.

IN the Scottish Court of Sessions an interim judgement was given on January 12th in certain proceedings which were taken by the Royal College of Physicians of Edinburgh against the Dr. Temple Company, Limited, of 7, West Register Street, Edinburgh—Harry Key (chemist), William Temple, Mathias Trudel (clerk), and John Key. The object of the proceedings, as appears from a report which was published in the *Scotsman*, is to restrain the respondents from using, in connexion with the business or businesses carried on by them at 7, West Register Street, Edinburgh, and 57, West Campbell Street, Glasgow, the name or title of "Doctor," or its contraction "Dr.," whether used in association with the names "Temple," "Temple Company," or "Temple Company, Ltd." or not; and to restrain them from pretending that they are medical practitioners or doctors, and from taking or using any title or description implying that they or any of them were persons registered under the Medical Acts or "specially qualified" to practise medicine in Scotland. In particular, the College ask that the respondents should be restrained from displaying certain advertisements upon their premises, and should be ordered to obliterate from the walls of the premises at West Register Street the name or title "Dr. Temple."

The respondents objected to the proceedings on two grounds. They said that the College were not so interested in the acts complained of as to give them in law a title to sue, and that the Medical Acts themselves provided a penal remedy which precluded civil proceedings being taken.

Lord Anderson granted the interim interdict asked for by the College, but limited its scope to Edinburgh, where alone, he considered, the College might be said to have an interest. He intimated that the point as to whether the College had in law a title to sue was one of importance and some difficulty which would be disposed of at a later stage, together with the question as to whether the acts of which the College complained constituted an infringement of the Medical Acts. The case, when finally disposed of, will raise, therefore, two points of very considerable medico-legal interest.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

UNIVERSITY COURT.

At the meeting of the Edinburgh University Court on January 17th the Principal, Sir William Turner, expressed the gratification of the Court that two members, Lord Provost Sir Robert K. Inches and Sir George A. Berry, had received the honour of knighthood and their regret that the two new knights were unable to be present to receive in person the congratulations of their colleagues.

Students and Military Service.

On the recommendation of the Senatus, it was resolved that students who had attested and had been accepted for military service, and who had completed five terms of study of anatomy, should be permitted to appear for the professional examination in anatomy in March next.

On the recommendation of the Senatus, it was resolved that, for the present year, students who commenced medical study in winter, and who are in their third year, should be allowed to appear for examination in March next, instead of in the following July.

Prize for Women Students.

It was announced that the sum of £237 had been received from the Scottish Association for the Medical Education of Women for the purpose of founding a prize for women medical students. The precise conditions of award will be announced later.

Examiners.

The following additional examiners were appointed:—*Public Health Laboratory Work*: G. P. Yule, M.D., B.Sc., M.O.H. Fifehire. *Pathology*: Professor H. R. Dean (Manchester). *Forensic Medicine*: W. G. Aitchison Robertson, M.D., F.R.C.P. Edin. *Public Health, etc.*: Charles Porter, M.D., B.Sc., M.O.H. Marylebone. *Midwifery*: G. Barbour Simpson, M.D., F.R.C.P. Edin.

UNIVERSITY OF ST. ANDREWS.

UNIVERSITY COURT.

At a meeting on January 22nd it was reported that the total number of students was 350; 144 men, a decrease of 88, and 206 women, an increase of 22. A number of men students of the Martinmas term had obtained commissions, and a large number were attested or awaiting commissions, so that it was expected that before the end of Candlemas term there would be

a reduction of about 100 in men students owing to military and kindred services, without reckoning those occupied in war work in the laboratories.

The Court concurred with the Edinburgh Court in appointing Professor Sir J. Halliday Croom to be a member of the Central Midwives Board for Scotland.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated:

FIRST EXAMINATION.—Alice Fung-a-Ling, A. F. Caddell, G. ap Vychan Jones, W. Gibb, D. Gilmour. *In Physics*: M. J. Quinlivan, Lizzie R. Clark, N. H. Mackay. *In Biology*: M. J. Quinlivan, R. B. Forgan, W. H. Kerr, M. H. Carleton.

SECOND EXAMINATION.—Eliza Jean Stuart, T. T. Read, C. T. Gasking, A. F. Brighlman, W. B. Watson, P. M. Fernando, G. P. de Silva. *In Anatomy*: A. B. Macdonald. *In Physiology*: J. K. Steel, D. Mackay, L. H. Fories, D. Levenstein.

THIRD EXAMINATION.—S. C. Swinburne, J. H. Brown, R. McLaren, W. B. Lawson, R. G. Battersby, B. Ajaji-Young, T. Jackson. *In Pathology*: F. G. Jones. *In Materia Medica*: A. B. Black, C. B. C. Moon, M. Talaat.

FINAL EXAMINATION.—T. C. MacGowan, C. A. Slaughter, T. C. van Derzeil, A. W. McGregor, C. K. Carroll, G. L. Pillans, W. L. Paterson, D. S. Taylor, D. S. Luther, D. S. Graham. *Medicine*: T. Jackson, J. Bygott. *Surgery*: R. C. W. Spence, B. C. Haller, J. E. Kitchen. *Midwifery*: A. Smith, junr., J. Ross. *Medical Jurisprudence*: H. Ellison, J. W. Gordon, S. W. Hoyland, T. Hardie, J. S. Durward, A. Morrison, J. V. R. Rohan, G. L. Stanley, J. Y. McLean, E. M. L. Morgan, B. J. T. Malcolm Gasper, W. B. Lawson, J. G. McK. Macaulay.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

Surgery: *H. H. Bailey, *†D. M. Hunt, †L. Kahan, *†G. L. T. Lawlor, †H. H. Lloyd, *†F. C. Russell, *†A. J. A. Wilson. *Medicine*: *†P. H. G. Bayon, *†C. B. de Forest, *†T. Y. Dent, *†J. Fox-Russell, †G. L. T. Lawlor, *†J. G. T. Thomas. *Forensic Medicine*:—G. S. Ashby, P. H. G. Bayon, C. B. de Forest, H. M. Gray, L. Kahan. *Midwifery*:—C. B. de Forest, H. M. Hobson, R. F. Jarrett, E. O. Morrison, R. H. Petterson, J. Remers, H. N. D. Richards, C. Segal, L. Zarchi.

* Section I.

† Section II.

The diploma of the society has been granted to the following candidates: C. B. de Forest, D. M. Hunt, G. L. T. Lawlor, I. H. Lloyd, T. C. Russell, J. G. T. Thomas, and A. J. A. Wilson.

Obituary.

DR. SAMUEL WHITE DUCKWORTH WILLIAMS, who died recently at the age of 75, was little known to the present generation, but the fruits of his work remain. He was the son of Dr. William White Williams, medical superintendent of the Gloucester County Asylum, who, with Dr. Conolly, was the pioneer of the present humane system of the treatment of the insane. Later these two were connected in this great work of reform with Sir Charles Bucknell and Dr. Hack Tukey. Dr. S. W. D. Williams was a student at St. Bartholomew's and matriculated at the London University. Owing to his father's illness he was unable to complete his course there, and ultimately took the degree of M.D. at St. Andrews. After assisting his father at Gloucester for a year, he was appointed assistant physician at St. Andrew's Hospital, Northampton, where he carried on his father's great work of reform and instituted the system of taking mental patients to the seaside for change of air and scene. Afterwards he was appointed assistant physician under Dr. Lockhart Robertson to the Sussex County Asylum at Haywards Heath, and in a few years succeeded him and was head of that great institution till 1888. It was largely due to his methods and skilful organization that that asylum became such a well known model of excellence and efficiency. Dr. Thomas Bodley Scott, to whom we are indebted for these notes, adds:

His writings were not many, but were of deep interest and always well thought out. His first publication, in 1866, was on the sedative action of digitalis in acute mania. The dose used is rather startling to the less courageous minds of to-day—"drachm doses of the tincture every two hours" till the attack was passed, but in such cases nothing but heroic treatment is of avail. His most important contribution was about the same period, and was the first systematic exhibition of bromide in epilepsy. This was begun at Northampton in 1864, and his statistics of successes and failures formed the groundwork of our present treatment of this disease. His investigations were always thorough, scientific, and unbiassed by undue enthusiasm. In addition to all the anxious and arduous work that the management of a big asylum involved, Dr. Williams found time for many other interests. He was a prominent Mason in Sussex.

He was a crack shot, a safe golfer, a good fisherman, and a good mountaineer; but perhaps the chief joy of his life was music, which he understood thoroughly. In his later failing years at Bournemouth his chief pleasure was in Dan Godfrey's wonderful orchestra. Here, with the full score of the chief symphonies before him, he forgot his physical troubles. He was a member of the Athenaeum Club for thirty years.

Though a very reticent and retiring man he was full of kindness, sympathy, and charity, and his friends all feel that by his death they have lost a most accomplished, courteous, learned physician and gentleman.

ON January 19th Mr. EDGAR HOWARD LAKE, B.Sc.Lond., demonstrator of anatomy at the Middlesex Hospital, lost his life as the result of a bicycle accident when he was on his way to the College of Surgeons, where he was going to present himself for his final examination. He was a man of high scientific attainments and devoted to his work. His ambition was to enter the Royal Army Medical Corps. By his premature death a man of great promise has been lost to the medical profession.

GEORGE MACDONALD, L.R.C.P. and S.Edin., who died suddenly (from angina pectoris) at his residence, 49, Murrayfield Gardens, Edinburgh, on January 14th, was for many years in practice at Markinch, Fife. He obtained his qualification of the two Edinburgh colleges in 1864, and was made L.M.Univ.Edin. in the same year. A few years ago he retired from active work and went to reside in Edinburgh. He had always taken a great interest in church matters, and soon after settling in Edinburgh he was elected an elder in St. George's U.F. Church. He was a good type of the quiet, hard-working country doctor, highly esteemed and greatly beloved. He is survived by a widow and a daughter. The funeral took place at Markinch on January 18th.

DR. JOHN LAING BRAY, who died in London, Ontario, on November 30th, 1915, was born in Kingston in 1841. He entered Queen's University as a student of medicine, and graduated in 1863. Afterwards he spent six months in Richmond, Virginia, where he served as surgeon in the Southern army during the American Civil War. In 1865 he went into practice at Chatham, where he remained until 1907, when he became registrar of the Ontario College of Physicians and Surgeons, a position he held until June, 1914, when he was obliged to resign on account of failing health. Dr. Bray was a member of the Ontario Medical Council from 1880 to 1907, in 1881 he was vice-president, and in the following year president. In 1891 he was elected to the presidency of the Canadian Medical Association. Dr. Bray always showed a great interest in the work of the profession, and as registrar of the Ontario Medical Council was well known and highly esteemed throughout the province.

DR. MALACHIA, of Milan, who recently died at the age of 80, was a gynaecologist of repute, but was best known as an advocate of social reform. He organized the first Italian congress of industrial hygiene and took a prominent part in the campaign against alcoholism and in the furtherance of cremation. In 1859 and 1860, and again in 1866, he served with Garibaldi and was awarded the silver medal for valour and the military cross of Savoy. He was a member of the Chamber of Deputies in three parliaments. Ten years ago he was made a Senator of Italy.

MR. J. G. GEORGE died at Buff Bay, Jamaica, on November 16th, 1915, at the early age of 38. He was the eldest son of Mr. Arthur George, of Kingston. When a student in Edinburgh during the South African war he joined the Royal Army Medical Corps and received the South African medal. He obtained the diplomas of L.R.C.P. and S.Edin., and L.F.P.S.Glasg., and in December, 1904, entered the medical service of Jamaica; he served for a time as one of the medical officers of the lunatic asylum, and was afterwards stationed at Buff Bay.

LIEUTENANT-COLONEL THOMAS MICHAEL O'BRIEN, R.A.M.C. (retired), died at Exeter on January 20th, aged 81. He took the diploma of L.R.C.S.I. in 1856, sixty years ago, and entered the army as assistant surgeon on January 22nd, 1858, becoming surgeon in 1870, and surgeon-major on March 1st, 1873. He retired on January 9th, 1889. The *Army List* assigns him no war service.

LIEUTENANT-COLONEL ALFRED JAMES O'HARA, Madras Medical Service (retired), died in London in December, aged 61. He was educated at the Bishop Cotton School at Bangalore, and at the Madras Medical College, where he took the L.M.S. He took the diplomas of L.R.C.S. and L.R.C.P. at Edinburgh in 1879, and entered the I.M.S. as surgeon on April 2nd, 1881; he became surgeon-major on April 2nd, 1893, and lieutenant-colonel on April 2nd, 1901, and retired on November 2nd, 1902. He served in Burma in 1886-88, taking part in the operations round Nyingyan and in those of the 3rd Brigade, and received the medal with a clasp.

LIEUTENANT-COLONEL WILLIAM MOYLE O'CONNOR, R.A.M.C. (T.F.), died in London on January 21st. He was a son of the late Mr. Patrick O'Connor, of Dublin. He was educated at University College and King's College, London, and at Trinity College, Dublin, where he became B.A. in 1886, M.B. and B.Ch. in 1887, and M.A. and M.D. in 1897. He also took the D.P.H. of the Irish Colleges, with honours, in 1889. He was for a time resident surgical assistant in the Meath Hospital, Dublin. He served for many years in the militia, and held the honorary rank of major in the army from April 1st, 1903. He became lieutenant-colonel commanding the 6th London Field Ambulance on March 31st, 1913, and was also in command of the Duke of York's head quarters school of instruction, and a member of the London Territorial Force Association. He was lecturer and examiner to the St. John Ambulance Association, medical officer of the Actors' Association, a Fellow of the Royal Society of Medicine, and a member of the British Medical Association. The interment took place at Glasnevin Cemetery, Dublin, on January 24th.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Berger, Sub-Director of the Pasteur Institute of Batavia, as the result of accidental inoculation in the course of experimental work on the prevention of plague; Dr. F. G. Byles, professor of hygiene in the University of Colorado, aged 62; Professor Andrea Ceccherelli, chief of the Institute of Clinical Surgery of the University of Parma, and director of the territorial Red Cross Hospital in that city; Dr. Edmond Chapuis, representative of the Jura department in the French Chamber of Deputies; Dr. Benjamin Joy Jeffries, of Boston, formerly ophthalmologist to the Massachusetts Charitable Eye and Ear State Hospital, aged 82; Dr. W. L. Ballenger, professor of laryngology, rhinology, and otology in the College of Physicians and Surgeons, Chicago, aged 54; Dr. C. L. Barrows, head of the gynaecological department in Cornell University, aged 58; Dr. Joseph J. O'Connell, health officer of the Port of New York, and lecturer on hygiene in the university of that city, aged 49; Dr. Rodolphe Engell, sometime professor in the Medical Faculty of Montpellier, professor of chemistry at the Ecole Centrale, aged 66; Dr. Hamelin, honorary professor in the Medical Faculty of Montpellier, aged 75; Dr. Peter Herescu, professor of urinary diseases in the University of Bucharest, aged 47; Dr. G. T. Jackson, professor of dermatology in the Women's Medical College, New York, author of several works dealing with matters connected with his speciality, aged 63; Dr. H. L. E. Johnson, professor of gynaecology in the George Washington University, Washington, and consulting gynaecologist to Providence Hospital and the United States Government Hospital for the Insane, representative of the Department of State at the International Congress of Hygiene held at Berlin in 1907, and at Budapest in 1909, aged 57; Dr. Maurice Langier, a former president of the French Society of Forensic Medicine; and Dr. J. G. Linthicum, sometime professor of the practice of medicine in the University of Baltimore, aged 81.

Medical News.

OWING to the death of the publisher, Signor Enrico Detken of Naples, the *Giornale Internazionale delle Scienze Mediche* has ceased to appear.

THE annual meeting of the Medical Sickness, Annuity, and Life Assurance Society will be held at the offices of the society, 300, High Holborn, W.C., on Tuesday, March 28th, at 4.30 p.m.

DR. JOHN CRUICKSHANK, Pathologist to the Crichton Royal Institution, Dumfries, and late assistant to the Professor of Pathology in the University of Glasgow, has been awarded the Foulis Memorial Scholarship by that university for distinction in original work in pathology.

SIGNOR SALANDRA, the Prime Minister of Italy, has, with the object of preventing waste of effort in the provision of aid and opportunities of re-education for the wounded, set up a committee comprising representatives of the services of public health and of the army and navy to study the best means of co-ordinating the work of public associations, institutes, and other public bodies for that purpose.

AT the annual meeting of the Liverpool Medical Institution on January 20th, Dr. C. J. Macalister was elected president, Dr. Llewellyn Morgan treasurer, Dr. Hubert Armstrong general secretary, Drs. John Hay and John Owen secretaries of ordinary meetings, Drs. Frank Barendt and J. Martin Beattie secretaries of pathological meetings, and Dr. R. W. MacKenna librarian and editor of the *Journal*.

AT the beginning of December the Italian Red Cross had established 31 hospitals at the front and 150 territorial hospitals, with 16,000 beds. It had mobilized 100 motor ambulances and 22 hospital trains. Besides these, it had at its disposal about a thousand automobiles, many of which were offered gratuitously for the work. The number of doctors was 1,500 and of nurses 2,000. The total personnel of the various services was 8,000.

THE American College of Surgeons, which has now about 3,400 Fellows in the United States and Canada, has recently announced that it has obtained from them an endowment fund of £100,000. The fund is to be held in perpetuity and the income only to be used to advance the purposes of the college. These are directly concerned with matters of character and training, with the betterment of hospitals, and of the teaching facilities of medical schools, and with laws relating to medical practice and privilege.

THE Central Midwives Board held its monthly meeting on January 20th, when Sir Francis Champneys presided. It declined to accede to requests of Queen Charlotte's and the City of London Lying-in Hospitals for the postponement of the operation of the new rules of training until January, 1917. In reply to a letter the Board resolved to ask the Essex County Council to reconsider a proposal to delegate its powers and duties under the Midwives Act, 1902. The names of eleven women were removed from the roll at their own request. A penal cases meeting was held on January 21st, when Sir Francis Champneys again presided. Eight cases were on the agenda, and four of the women were charged with not being of sober habits. Seven out of the number were struck off the roll, and in the eighth case judgement was postponed for reports from the local supervising authorities in three and six months.

THE Right Hon. Henry Hobhouse has been appointed Chairman of the Departmental Committee of the Board of Agriculture on the settlement and employment on the land of discharged soldiers and sailors, in the place of Sir Harry Verney, Bt., M.P., who has received a commission in the army. Mr. H. L. French, of the Board of Agriculture, has been appointed secretary of the Committee. Sir Rider Haggard is about to start, as representative of the Royal Colonial Institute, on a mission to the Dominions for the settlement of ex-service men from the United Kingdom on the land overseas at the conclusion of the war.

IN a German work, an English translation of which has been published recently under the title *Emergencies in Medical Practice*, the author, one Dr. Richard Lenzmann of Duisberg, with a truly prophetic instinct, devotes a chapter to "Poisoning by irrespirable gases," in which he deals at some length with those that "distribute a peculiar odour," to quote the translator's curiously un-English words. Into this group would of course fall chlorine, bromine, ammonia, and other asphyxiating and lacrymogenic gases on which German scientists are entitled to

speak with the authority begotten of close study and accurate knowledge, inasmuch as the manufacturers of these gases for use in warfare never supposed that they would have to defend themselves against the consequences of their inhalation, an assumption which has not been borne out by events. It was certainly thoughtful on the author's part to discuss at length the question of treatment. No information, however, is vouchsafed as to the means of guarding against the effects of irritating gases, and the suggestions for treatment, even of such comparatively mild gases as carbonic oxide, coal gas, and sulphuretted hydrogen, are by no means up to date. Possibly the manuscript was censored in intelligent anticipation of coming events, otherwise it is difficult to account for the author's omission in this respect.

In the nineteenth annual report (for 1914) recently issued of the National Association for the Feeble-minded (Denison House, Vauxhall Bridge Road, S.W.) it is stated that the war has interfered with the establishment of institutions which the Mental Deficiency Act made it the duty of local authorities to supply, and that consequently accommodation furnished by existing voluntary homes was taxed to the full. The Princess Christian's Farm Colony at Hildenborough had provided an additional farm house designed "for boys of a slightly better social class." The older buildings urgently needed certain additions in the way of day-space, and in order to provide this an appeal is made for £500, failing which the alternative facing the Committee would be to discharge some twenty of the existing inmates. Several additional homes (notably those established by the Rev. H. N. Burden and his Incorporated Society and the Co-operative Sanatoriums at Billericay) have entered into federation with the National Association, and steps were taken to promote closer unity amongst federated homes for mutual help, counsel, and guidance. Two conferences with this object had been held, and the opinion was strongly expressed that in addition to large public institutions under the Act the continued existence of smaller voluntary homes was most desirable. During the year communications had been addressed to the managers of rescue homes with reference to the distinctive classification of feeble-minded inmates, and the prevalent absence of such classification had been brought under the notice of the Board of Control. The report states that 673 applications had been dealt with in the twelve months preceding its issue. Notes are also given concerning some of the homes in connexion with the association, the complete list of which shows aggregate accommodation for over 2,000 inmates in 25 voluntary establishments, either "certified" or "approved" under the Mental Deficiency Act.

THE Central Association for the Care of the Mentally Defective (30 and 31, Queen Anne's Chambers, Tothill Street, S.W.) originated at a meeting called by the National Association for the Feeble-minded in November, 1913, when it was resolved to form a "central organizing body representing the statutory authorities concerned in the care of defectives and the voluntary institutions, homes, and societies dealing with defectives, both directly and incidentally, in the course of their social work." It was subsequently incorporated under the Companies Act, and among the objects set forth in the memorandum of association are the promotion of suitable treatment of mental defectives in England and Wales, the rendering of assistance (when requested) to public authorities in carrying out the Acts relating to defectives, and the formation of local branches in the various statutory areas. It is designed also to serve as a means of communication between local voluntary organizations and Government departments and local authorities. It will seek to organize the training of teachers, visitors, guardians, attendants, and others concerned in the care of defectives, to give assistance in the case of individual defectives not under statutory authorities, and to keep records of such defectives and of societies and institutions dealing with defectives. From the first report of the council (which deals with the period to July 22nd, 1915) it appears that considerable progress has been made in carrying out these objects in spite of difficulties caused by the war; twenty-five local voluntary associations have been formed, a scheme of training for special teachers has been drawn up and submitted to the Board of Education, and a course of instruction for visitors and officials established. The Board of Control has recognized the practical work done by the association and shown its confidence therein by financial grants under Section 43 of the Mental Deficiency Act to the amount of £300. The report closes with an interesting account of the summer school for teachers of mentally defective children held under the auspices of the association in July last.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attilage, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

LETTERS, NOTES, ETC.

EPILEPSY.

DR. A. G. CRIEB (G.M.O., Millthorpe, N.S.W.) writes: Some years ago one of my patients, a rheumatic subject, who used methyl-salicylate ointment frequently for lumbago, told me that it acted like a charm when rubbed into his chilblains. I followed this clue, and have long ago come to the conclusion that chilblains in the majority of cases are due to uric acid, and I treat the patients accordingly. A purin-free diet, a mixture of sodium salicylate and potassium bicarbonate with cascara, and the methyl-salicylate ointment rubbed well in night and morning, will quickly relieve the patient. In the JOURNAL of October 23rd, 1915, Dr. Mercier discusses the value and necessity of bromides in epilepsy. The late Sir William Gowers introduced borax in this disease, and I always combine it with the bromides. I am of opinion that a purin-free diet with a rural life is of more importance than the administration of drugs.

WHOOPIING-COUGH AND KINKHOST.

WITH reference to a note under this heading which appeared in the JOURNAL of January 8th, p. 76, Dr. J. A. Nixon, of Clifton, refers to Hecker's *Epidemics* (Sydenham Society, 1844, p. 219) for an account of the origin of the term "Coqueluche" as applied to whooping-cough. Hecker adds little to the authorities quoted in the note. In an account of epidemics of influenza he says: "The French, who, from the levity of their character [Hecker was, of course, a German], have always called serious things by jocose names, designate this disease *Coqueluche* (the monk's hood), because, owing to the extreme sensibility of the skin to cold and currents of air, this kind of hood was generally necessary, and was a protection against an attack of the malady as well as against its increase." The term was first employed during a severe epidemic in Paris in 1414 in which all who had the complaint suffered from hoarseness, and all public business was interrupted. This is the epidemic of which Mézeray speaks in his *Abregé chronologique de l'histoire de France* (Paris, 1690), where he says: "Un étrange rhume qu'on nomma coqueluche, lequel tourmenta toute sorte de personnes, et leur rendit la voix si enrouée que le barreau et les collèges en furent muets." The word *coqueluche* was afterwards applied to whooping-cough. To Hecker's reference we may add the following: Kurt Sprengel in his history of medicine (French translation by A. J. L. Jourdan, second edition, Paris, MDCCCXV, t. iii, p. 85) says *coqueluche* was by some connected with *cucullio*, a hood, while others derived it from *coquelicot*, the wild poppy, because the syrup of that plant was first used in the treatment of the disease. Skeat may also be quoted (*Etymological Dictionary, sub voce*): "Chincough, the whooping-cough. (E). 'No, it shall ne'er be said in our country Thou dy'st of the chin-cough' (Beaumont and Fletcher; *Bonduca*, 1. 2). It stands for *chink cough*; prov. Eng. and Scot. *Kink-cough* or *kink-host* where *host* means 'a cough.' Cf. Scot. *Kink*, to labour for breath in a severe fit of coughing (Jamieson). It is an English word, as shown by 'cincing, cacinatio' in a glossary, printed in Wright's *Vocab.*, 1, 50, col. 2; which shows that *kink* was also used of a loud fit of laughter. *Kink* is a nasalized form of a root *kik*, signifying 'to choke,' or 'to gasp'; an imitative word like *Cackle*, . . . + Du. *Kinkhoest*, the chincough, whooping-cough; O. Du. *Kiechhoest*, *Kichhoest*, the same (Kilian). + Swed. *Kikhosta*, the chincough; *Kik-na*, to gasp, to pant (where the *n* is formative, to give the word a passive sense, the lit. meaning being 'to become choked'). + Dan. *Kighoste*, the whooping-cough. + G. *Keichen*, to pant, gasp. B. A stronger form of this root *KIK*, to gasp, appears in the English *choke*. . . . Indeed, the word *cough* is also related to it."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

ANTENATAL CLINICS AND PREMATERNITY PRACTICE AT THE EDINBURGH ROYAL MATERNITY HOSPITAL IN THE YEARS 1909-1915.

By J. W. BALLANTYNE, M.D., F.R.C.P.E.,

PHYSICIAN, EDINBURGH ROYAL MATERNITY HOSPITAL; LECTURER ON MIDWIFERY AND GYNAECOLOGY, SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH, ETC.

In November, 1901, prematernity work was definitely commenced in the Edinburgh Royal Maternity Hospital with the opening of the Hamilton Bed—a bed set apart and endowed for the purpose of the treatment of the diseases peculiar to, or accidental during, pregnancy. A few years later, with the consent of the directors of the hospital, the bed became a ward, and was known as the "prematernity ward"; and I have from time to time reported on the work done therein, sometimes in the form of descriptions of special cases, and at other times in that of lists of maladies dealt with. My last report, which summarized the cases treated in the autumn quarter of 1908, appeared in the February and March parts of the *Journal of Obstetrics and Gynaecology of the British Empire* for 1909.¹ Since 1908 I have continued to be in charge of the hospital during the autumn quarter of each year, and I now bring forward notes on the cases dealt with during these seven recurring periods in the pre-maternity ward.

Before, however, the records of these experiences are set forth it may be useful and interesting to outline the extensions of the prematernity and antenatal work of the hospital during the past few years. No sooner had the prematernity ward been opened than it became evident that patients entering it were being supplied from at least three different sources—medical men in and around Edinburgh, knowing of its existence, began to send in suitable cases, and in this manner the majority of the women arrived for treatment; a few patients apparently came on their own initiative; and others were recommended to come in by the nurses of the hospital who happened, in the discharge of their duties in the outdoor department, to meet with expectant mothers suffering in one way or another from the maladies of gestation. The result was that almost automatically the prematernity work began to develop along these three lines; and, as a consequence, I have never had any lack of cases during the autumn quarter in the last seven years, and in the last three or four years the supply of patients has been such as to force me to accommodate some of the incomers in another small ward of four beds known as the "first stage ward." A few have had to be temporarily placed in the large general wards of the institution.

The extension of the supply of patients through the dissemination of information regarding the existence of the prematernity department has been gradual and continuous. The publication from time to time in the medical journals of the result of cases treated in the hospital has no doubt tended to make the work familiar to a large circle of medical men, and the district served by the hospital has thus been widened, so that in 1914 several patients from long distances were inmates of the ward for longer or shorter periods. As other maternity hospitals establish the same kind of work this source of supply may cease to expand so rapidly.

Antenatal Work in the Extern Department.

Another direction of development has been through the extern department of the hospital and the nurses working in it. At first antenatal work in this sphere was irregular, haphazard, and on a small scale; individual pregnant women occasionally came to the hospital to put down their names to secure attendance at their confinement, and at the same time asked advice in connexion with troubles from which they were suffering, with the result that now and again one would enter the prematernity ward; and nurses, on their rounds in the extern department, sometimes heard of women whose pregnancies were not proceeding normally, and got into touch with them, either giving them advice in minor matters or bringing them into hospital in more serious cases. During the autumn quarter of 1913²

this sort of work was systematized and considerably extended. I then made arrangements whereby a trained nurse with special knowledge of pregnancy troubles was made available for work in the "district" (as the extern department is called), and she visited expectant mothers, giving advice as to the preparations for confinement, making inquiries respecting health, and in particular taking notice of any of the danger signals of the pregnant state, such as headache, oedema of face and hands, excessive vomiting, rickety deformities, and the like. She reported to the matron and the medical staff in the hospital. In cases of grave trouble the patient was brought into the prematernity ward, and in less serious cases she was visited by one of the resident medical officers, and watched over by the pregnancy or prematernity nurse in her own home. Most of the patients with whom the hospital thus got into early touch were married women, the unmarried girls reaching the institution through another channel, to which reference will be immediately made.

In order to aid the prematernity nurses in their work among the expectant mothers of the extern department I constructed and had printed a Prematernity Card, setting forth the most important questions to be inquired into and reported upon. These cards were put into use in September, 1913, and were soon found to be of great value. Each card (*vide infra*) had spaces for answers to questions regarding, first, certain general

PREMATERNITY CARD (Edinburgh Royal Maternity Hospital).

1. Name
2. Age.....
3. Address.....
4. No. of Pregnancy
5. Details of past pregnancies, labours, nursings, etc.
6. Expected Date of Confinement
7. Details of present pregnancy, especially as to danger signals:
 - (a) Excessive vomiting.....
 - (b) Persistent headache.....
 - (c) Small quantity of urine.....
 - (d) Discharge, red or white.....
 - (e) Excessive constipation
 - (f) Impaired vision
 - (g) Any other unusual sign, for example, swelling of hands and face.
8. Advice given as to
 - (a) Food. (b) Clothing. (c) Exercise and rest.
 - (d) Straining or reaching. (e) Medicines.
 - (f) Care of breasts and teeth. (g) Medical advice. (h) Preparations for Confinement and baby clothes. (i) Healthy living rooms.

matters such as name, age, and address of patient; second, the number of the pregnancy, the details of past pregnancies; and the expected date of confinement (that is, the age of the gestation); third, the details of the present pregnancy, especially in respect of such danger signals as excessive vomiting, persistent headache, diminished flow of urine, red discharge, excessive constipation, impaired vision, and the like; and fourth, regarding the advice given by the prematernity nurse as to food, clothing, exercise, rest, straining, medicines, care of breasts and teeth, medical advice (at the hospital), preparations for confinement (in the home), and the like. After filling in the answers to the preliminary questions the visiting nurse was instructed simply to place a cross opposite any one or more than one of the danger signals, and similarly to put a mark opposite the advice she had given. For instance, a card might be returned with a cross opposite "impaired vision," and another alongside of "medical advice"; as the result of the reception of this card one of the medical officers would visit the woman, would probably find that she was suffering from albuminuria and retinitis, and would be able to take such measures as might save her from eclampsia. The patient might have noticed her failing eyesight, but might not have thought of telling the nurse about it had not the question been directly put to her. As a matter of fact such a case occurred in the extern department of the hospital simply as a result of the prematernity nurse asking questions, and this case had not a little to do with my determination to provide the card of inquiry.

As has been stated, married women were the patients most effectively reached by the prematernity nurses. They heard of them when visiting other patients, and,

after finding out that they were not already being looked after by doctor or midwife, they offered their advice, often with the result that timeous arrangements were made for confinement, baby clothes were looked after, and many other preliminaries carried out which would otherwise have been postponed or never done at all. Reference has been made to the way in which the unmarried girls were reached. In this respect the hospital was very fortunate in having situated opposite to it the Lauriston Place Home for Maternity Rescue Work. In this institution³ young girls illegitimately pregnant for the first time are cared for, and in many cases saved from the further disasters which so often follow upon such lapses from virtue; but, further, these girls are kept under medical supervision, a medical man regularly visiting the home, and watching for early signs of the maladies of pregnancy. In this way deviations from the normal have been on many occasions promptly recognized; in some instances the requisite treatment has been applied in the home with immediately beneficial results, whilst in others the girl has been transferred to the prematernity ward of the adjacent Royal Maternity Hospital for the more specialized management which the morbid condition called for. It is an undoubted fact that by this means many primiparous patients have in recent years been protected from the development of eclampsia, and have been carried safely through their confinements, who would otherwise have suffered severely and might well have lost their lives. There can be no hesitation in saying the Prematernity Rescue Home and the prematernity ward in the Royal Maternity Hospital have worked most usefully into each other's hands, and have by their conjoined efforts saved many lives and lessened much suffering.

ANTENATAL WORK IN THE HOSPITAL.

During the summer of 1915 a further advance was made in the organization of the prematernity and antenatal work carried on in the Royal Maternity Hospital. This consisted in the establishment of a weekly antenatal clinic, under the care of the physician or the assistant physician of the hospital for the time being. Two rooms were set apart and fitted up for the purpose, and in them regular antenatal clinics were commenced in June, 1915, under the care of Dr. Haig Ferguson, whose quarter it was. When I came on duty on July 1st the work which had been so auspiciously begun was continued, and Dr. Oliphant Nicholson, the assistant physician, saw many an interesting case of disease in pregnancy during the following three months. Some cases were immediately taken into the prematernity ward, others were treated at the clinic, and yet others at their own homes in the extern department, and others again were simply asked to report themselves at intervals for supervision. Another weekly clinic was instituted at the same time for infants recently born in connexion with either the indoor or the outdoor work of the hospital, and so post-natal is added to antenatal care of the babies. The directors of the hospital present to each of the expectant mothers visiting the clinic a copy of my little booklet (*Hints to the Expectant Mother on Her Health*), published in 1915 by the Women's Co-operative Guild of London. This has also been freely used in the extern department of the hospital, and has to some extent taken the place of the prematernity cards above referred to. Through the antenatal clinic there can be no doubt that the hospital comes into more immediate and earlier touch with just the patients who may be most benefited by prematernity care and treatment. It has, so to say, completed the prematernity system of the hospital.

During the autumn quarter of 1915 a number of interesting cases were dealt with in the antenatal clinic. There were two or three patients suffering from albuminuria; a heart case which was taken into the prematernity ward; an instance of excessive vomiting which was treated; a woman troubled with haemorrhoids, who was relieved; one with a contracted pelvis, who was told to come into hospital for induction of labour in a month; one who had had repeated miscarriages and whose past history in respect of syphilis was investigated; one who had given birth to dead infants, who was kept under observation; one who had had spurious pains and was assured of the fact; one who had had "fainting turns" from an undiscoverable cause, who was to be visited; one who was distressed by cystitis, and was given medicine; one who had chronic

constipation, which was overcome, and one whose pregnancy was doubtful. There were also cases of normal pregnancy, in which the mothers simply came for advice about their arrangements. There can be no doubt regarding the real value of these antenatal clinics, for through them the physician on duty gets to know of the health of pregnant women who will later become his patients in either the intern or extern departments of the hospital; his diagnosis and prognosis, and to some extent his treatment of the resulting confinements, are rendered more exact and much more effective, and the patients' chances of normal labours rendered better than they would otherwise be. Further, when more normal non-war times come, the teaching value of the clinic for undergraduates and post-graduates will be demonstrated more fully. Certainly opportunities for the careful diagnosis of normal, and especially of abnormal, pregnancies are thus greatly extended.

The Prematernity System.

The prematernity system of the hospital as it now exists may be described as follows: The prematernity ward is the centre of the whole work, for without it all the rest would be ineffective. The other means would not indeed be useless but they would be indecisive, and patients would be left in many cases incompletely dealt with. Consequently the other parts of the system are largely of the nature of sources of supply for the prematernity ward. They consist in the first place of the prematernity or prenatal nurses (to use the name given to them in Boston where they work under the Women's Municipal League), who come into touch with expectant mothers in the outdoor department of the hospital, and who, if necessary, recommend these "expectants" either to the antenatal clinic or to the prematernity ward. In the second place, there is the prematernity home for unmarried girls, where such young pregnant women are kept under medical supervision, and can be sent either into the general wards when they pass into labour, or into the prematernity ward if they develop serious complications of gestation; in the third place, of the antenatal clinic, whose range of usefulness has already been indicated, and need not be restated; and, in the fourth place, of the medical practitioners in the neighbourhood, who, with steadily increasing frequency, are sending suitable patients of the working class into hospital for prematernity treatment. The prematernity department of the hospital, naturally, is connected with the maternity portion, where the women are delivered of their infants and pass the days of the puerperium, and that again is reinforced by the baby clinics, to which the mothers are enjoined to bring their infants for supervision, weighing, and advice, and by the postnatal home for the unmarried mother and her first child.⁴ At the same time these agencies are not necessarily all brought into action in any case. It is not essential, for instance, that a woman treated in the prematernity ward wait in the hospital for her confinement; she may be relieved of her trouble while in the pregnancy ward, and thereafter return to her own home for her confinement; and this is a not infrequent occurrence in the case of maladies early in pregnancy, such as threatened abortions and troublesome vomiting.

PREMATERNITY WARD WORK, 1909-1915.

In the remaining part of this contribution I shall not try to give a complete account of the work done in the prematernity ward in the Edinburgh Royal Maternity Hospital during the autumn quarters of the seven years from 1909 to 1915, for that would constitute a very lengthy statement; but I shall give the numbers of the patients attending in these quarters, indicate the maladies from which they suffered, and a few notes in connexion with specially interesting cases.

Autumn Quarter, 1909.

In the autumn quarter of 1909 thirty-two patients passed through the prematernity ward. The following were the causes by reason of which these women were treated in the ward for morbid pregnancies: Of albuminurias there were five, and of eclampsias three, and to these eight cases special reference is made below. Three were received on account of varicose veins, three by reason of false pains, three for the induction of labour on account of

small size of the pelvis, three for heart disease, and three for convenience (homelessness, poverty). Two patients were admitted for threatened abortion, in both of whom the pregnancy continued. One patient was taken into the ward on account of symptoms arising from over-distension of the abdomen, which turned out to be due to twins; one for syphilis complicating pregnancy; one for a cervical cyst which it was feared might interfere with labour, but did not; one for inevitable abortion; one for phlebitis; one for croupous pneumonia; and one for an ovarian tumour, which was removed a few days later in the Royal Infirmary, where she was sent.

Whilst the maladies named were the outstanding ones from which the patients suffered, they were not the sole ones. For instance, one of the women, whose most evident trouble arose from varicose veins, had in a previous pregnancy been attacked by eclampsia; another, who is numbered with the albuminurias, came in for false pains; and the existence of a cervical cyst was quite accidentally discovered in another, who came to the hospital from the poorhouse.

Of the thirty-two mothers one only died. This was the patient sent in suffering from croupous pneumonia. She arrived in an ambulance from a town some miles out of Edinburgh, and was practically moribund on her arrival. She was put on oxygen inhalation soon after her admission, and was vigorously treated by stimulants and other appropriate means, but all the measures taken were ineffective, and she died undelivered. She was not at term. Of the remaining thirty-one mothers, six left the hospital undelivered but relieved of the maladies for which they were admitted; the six included the cases of threatened abortion, of varicose veins, and of false pains. Another undelivered woman (the one suffering from an ovarian tumour) went to the Royal Infirmary for ovariectomy. Twenty-four patients remained in or returned to the hospital for confinements, and they all left the institution in good or fairly good health after their deliveries. One death in thirty-two was a result which could be considered satisfactory when it was borne in mind that there were three eclampsias, five albuminurias, three heart cases (one of which was a very serious one), and a croupous pneumonia. The heart case just referred to was so grave that labour had to be induced; she lived for two years afterwards. The results so far as the infants were concerned were not so good; they numbered twenty-six, for in one case there were twins. Of the twenty-six, sixteen were alive when their mothers left the hospital, and to these might be fairly added the seven fetuses still unborn in the seven patients who left the institution undelivered; but the remaining ten died, eight of them antenatally, one during birth (from craniotomy), and one (a prematurely born child from a case of induction) some days later in the post-natal period. Of the eight antenatal deaths one was an abortion, one was due to syphilis, two were the result of eclampsia in the mothers, one fetus perished *in utero* (in the case of the maternal death), one death was due to maternal albuminuria, one to maternal heart disease (probably placental haemorrhage), and one from an unknown cause (prematurity?).

Nearly all these prematernity cases contained elements of interest in their records; but space can only be given for a brief reference to the three cases of eclampsia.

The first of them, a primipara, aged 25 years, was a few days short of the full term, and was sent to hospital after having had seven fits. On admission her blood pressure was 160, her pulse 91, and her temperature 99. Venesection was performed, the stomach was washed out with sodium bicarbonate solution, 10 oz. of Henry's solution were inserted into the stomach, a large enema was given, and normal saline was transfused subcutaneously. Improvement followed, and three days later she went into labour and was safely delivered of a living child. She had no fits after admission to the ward, and both she and her baby left the hospital well.

The second eclampsia patient was also primiparous, her age was 27, and her pregnancy was in the eighth month. She was sent into the hospital after having had five fits, and she had one after admission. The treatment consisted of stomach washing, the administration of 10 oz. of Henry's solution by stomach tube, a large enema, and the hot pack. She soon began to improve, and five days later she went into labour and was delivered of a dead-born male child, whose weight was only 4 lb. 2 oz. The mother made a good recovery. The third patient had a somewhat unusual experience, and it was a consideration of her case which led me to extend the treatment I was in the habit of giving in eclampsia to albuminuric patients who had not yet developed fits. She was only 17 years

of age; it was her first pregnancy, and she had reached the seventh month; she was sent into the prematernity ward on account of generalized oedema, diminished secretion of urine, and marked albuminuria. She had had no fits. I contented myself with ordering purgatives, diuretics, the hot pack, and an enema, and for five days there was steady improvement; then her blood pressure rose to 170, the fetal movements ceased, and the patient had a fit. On the following day she had two fits, and then venesection, intravenous transfusion (normal saline), stomach washing, and the running in of Henry's solution was performed. Improvement in certain of the symptoms followed, but she continued in a dangerous state for two days, at the end of which labour set in, and she was delivered of a dead male fetus, weighing 2½ lb. She made a slow but in the end a good recovery.

This last case was in one sense a disappointment, for I had hoped—and, indeed, had affirmed in teaching students and post-graduates—that if an albuminuric patient came into the prematernity ward and received treatment there for at least two days eclampsia could be staved off. In this instance eclampsia was not prevented. The lesson I learnt was to give to grave cases of albuminuria the same treatment, or part of it, as I was giving to actual eclampsias. In future I treated the serious cases of pre eclampsia just as if they had already had fits, sometimes doing a venesection, sometimes adding to that a gastric lavage with sodium bicarbonate solution, and sometimes transfusing as well. The change in management was simply a carrying of the principles of preventive treatment a little further back in the history of the case. In other words, I did not wait for the fits to develop before giving the treatment I thought necessary for them.

Autumn Quarter, 1910.

In the autumn quarter of 1910 twenty-nine patients passed through the prematernity ward. The conditions leading to their admission to the ward were as follow: Four were admitted for convenience (poverty, homelessness), three on account of albuminuria, three for the induction of labour on account of contraction of the pelvis, and one to wait for a Caesarean section for the same reason, two for spurious labour pains, two for heart disease, and one each for jaundice, retroversion of the gravid uterus, eclampsia, pyelonephritis, hyperemesis, oedema of limbs, haemorrhage at eighth month, haemorrhage at seventh month, syphilis and perhaps myxoedema, supposed appendicitis, threatened abortion, and diarrhoea and vomiting. There were two other interesting causes for admission. One was the occurrence of fetal death in previous pregnancies, and the other was the supervention of convulsions (soon after birth) in the infants born at previous labours.

All the mothers did well. Seventeen of them remained in the hospital for their deliveries, whilst twelve, for various reasons, left undelivered, but, as a rule, relieved of the trouble for which they were admitted, or remained for further treatment during the ensuing quarter. Of the seventeen mothers who went on to labour, fourteen gave birth to living children who left the hospital alive, whilst one (an albuminuric patient) expelled a dead fetus, one (a hyperemesis case) had abortion induced, and another (a woman with a contracted pelvis, especially narrow at the outlet) lost her child in labour. The last named case caused me more regret than any other during the quarter.

The woman had had four previous full term labours. With the help of forceps her doctor had delivered her of her first child, who, although in a state of asphyxia at the time of birth, had survived; but in the three following labours, which were all instrumental, the child was lost in each case. She had been warned to return to the hospital for induction on the occasion of her last labour, but she did not come in till she was in the eighth month. The interspinous diameter measured about 9 in. and the intercrural about 10 in., whilst the true conjugate was calculated to be a little over 3 in.; the outlet felt markedly narrow. It was regarded as a just minor type of deformed pelvis. Labour was induced, but both forceps and version having failed the child had to be craniotomized.

Two causes must be assigned for the untoward result. The first was a miscalculation of the possibility of the child passing through the pelvis, owing in part to the late date of induction, in part to the large size of the fetus, and in part to the unrealized narrowness of the outlet; and the second was the fact that in her first labour a living child was extracted with the help of forceps.

During this quarter a good deal of post-graduate

teaching was carried on in the hospital,* and I gave several clinics in the prematernity ward; one of these lectures was reported in the *International Clinics*.⁶ In it I gave an account of three interesting cases.

One was an instance of recurrent fetal death in a patient who in each of her three previous pregnancies was delivered of a child which had evidently perished *in utero* about a fortnight before its expulsion. She was pregnant for the fourth time, and besides watching the fetal heart carefully I ordered her to have calcium chloride and a mixture containing iron, arsenic, and strychnine. She went a little beyond the full term, and so I induced labour, and had the satisfaction of delivering her of a living child.

Another woman was successfully treated for retroversion of the gravid uterus causing difficulty in micturition; the uterus was replaced under an anaesthetic, and a pessary was introduced to keep it in position.

The third patient suffered from renal calculi and pronephrosis in pregnancy; she was operated on in the Royal Infirmary, the kidney being opened and the stones removed (nephrolithotomy); she then returned to the prematernity ward, where she remained till her labour, which took place normally; both mother and infant left the hospital in good health.

Amongst the cases treated at this time there was a curious one in which a patient was sent into the ward from the country by a doctor who reported that in each of her previous pregnancies (five in number) she had given birth to a living child which in every instance died from fits some weeks later. In one instance a *post-mortem* examination was made, which did not, however, reveal any cause for the fits. Her medical man (Dr. Andrew, of Windygates, in Fife) thought that perhaps some antenatal treatment might be administered through the mother which would prevent the next infant dying in the same way as the former ones. A very close examination of every one of the woman's systems was made, without, however, leading to the discovery of any anomaly in the working of any one of them. Thinking that perhaps the fetus might have suffered in previous pregnancies from deficiency of calcium salts or of phosphorus, I put the mother on hypophosphite of calcium and sodium, and after a stay in the ward of about a week she returned to her home to be under Dr. Andrew's care. I heard later from Dr. Andrew that once again she had given birth to a living and apparently healthy child who had developed fits at the end of a week. Treatment before birth, therefore, was of no avail in this case, but I have recorded it as of interest and as illustrating the sort of case which the prematernity ward attracts to the hospital and the new vistas of possible kinds of treatment it suggests.

Autumn Quarter, 1911.

In 1911 my quarter on duty in the maternity hospital was reduced by two weeks, in order to facilitate a re-adjustment of the terms of service of the medical staff; consequently, the number of patients who passed through the prematernity ward was reduced to 26. These patients came in for various causes. Three were admitted because they were supposed to be aborting, and two of them did abort, whilst the other was curetted when it was discovered that she had already expelled most of the gestation sac. Another patient was sent because of repeated premature labours with dead children; she did well. There were 5 cases of albuminuria; all these did well under appropriate treatment, with the result that the five mothers left the hospital in good health along with six children, for one of the labours ended in the birth of twins (with hydramnios). In one of these albuminuric patients there had been chorea in the early months of pregnancy (for which she had been treated in the prematernity ward); in the twin case the united weight of the infants was 10 lb. 5 oz., and in the remaining 3 cases the child weighed 8 lb. 6 oz., 8 lb. 13 oz., and 7 lb. 15 oz. respectively. It was therefore probable that in 4 of the cases the cause of the albuminuria was mechanical pressure or renal strain.

There were 3 cases of hyperemesis, and in all of them it was found necessary to induce abortion. Consequently all the fetal lives were lost, and there were four of them, for in one of the pregnancies there were twins. This was an unfortunate result; but in addition I had to deplore the death of one of the mothers. The fatal case was one of a woman, aged 40, pregnant for the fifth time (at the

fourth month). Her pulse was 110 when she was admitted, and it never fell below 100 either after or before the induction, and death occurred seven days *post abortum*. Another patient was sent in for gastric disturbance near the close of pregnancy; but she had a normal labour and a living child. There was some (unconfirmed) suspicion of gastric ulcer. Two women came in on account of troublesome constipation; both were relieved by appropriate treatment; one went out undelivered, as she was not near term, and the other remained in hospital for her confinement, which was normal. Two patients came in for spurious pains; in one case they settled down and she went out, her pregnancy continuing; in the other she went out, returned exactly fourteen days later, and had her baby normally.

Two patients were in the prematernity ward by reason of contracted pelvis. One of these women went into labour spontaneously and prematurely, while waiting in the ward, and had a living child who survived; the other, who had had Caesarean section on a previous occasion and had developed a large umbilical hernia, was kept in till full term, when I performed a second Caesarean section along with an operation for the closure of the hernia; both were successful. Of the remaining seven cases, one was admitted after a fall in pregnancy and an attack of haematemesis, but since no evil results followed she went home in eight days; one came in for bronchitis and varicose veins, and after a stay of a week was delivered naturally, with immediate improvement in the two morbid states; one was sent in for oedema of the legs, and after twelve days gave birth to a child weighing 9 lb. 6 oz., a circumstance which probably accounted for the oedema; one was given a bed for nearly a fortnight on account of threatened accidental haemorrhage, but since the red discharge did not return she went home for her confinement, which was not due for some weeks; one was sent up to the hospital on account of mental symptoms, and whilst in the hospital she tried to drink a bottle of lysol, but she became normal after her confinement, which, however, was three weeks post-mature; and another was admitted on account of phlebitis of the left leg which threatened to develop into phlegmasia alba dolens of pregnancy, but which, with rest in bed and other appropriate treatment subsided and was followed by a normal labour and puerperium. The last-named patient also suffered from an abscess in the leg which Mr. Wade (from the Royal Infirmary) opened after her confinement. The seventh of these cases was an interesting example of haematuria during pregnancy.

The woman was a III-gravida at the eighth month; for more than two months blood had been coming in the urine, and she had received treatment from her doctor, but lately the haemorrhage had been alarming, and it was so during the first five days after her admission to the hospital. As the cause was obscure, I asked Professor Caird (the consulting surgeon of the hospital) to see her with me. The result of a cystoscopic examination was the discovery of an ulcer at the fundus of the bladder, covered with a blood clot. Since she gave a positive von Pirquet reaction it was regarded as probable that the ulcer was tuberculous in nature. But whatever may have been the explanation the blood gradually diminished in amount, was quite gone eleven days later, and the patient had a normal labour and puerperium and a healthy male child weighing at birth 8 lb. 4 oz.

The results of the prematernity ward work for the autumn quarter of 1911 may be summed up as follows: Twenty-six mothers were under treatment; of these, 5 left the hospital undelivered but relieved of the trouble for which they entered; 1 died (the case of severe hyperemesis gravidarum); and the remaining 20 passed through labour and left the hospital well. In all there were 28 babies or fetuses, for in two of the confinements twins were born; of 5 of these nothing can be said, for the mothers went out before delivery; 7 fetuses (including one pair of twins) perished, but they were all non-viable; and the remaining 16 (including the second pair of twins) were all alive and well when taken from the hospital by their mothers.

ON THE IMMEDIATE TREATMENT OF SEVERE POST-PARTUM HAEMORRHAGE.

BY

R. K. HOWAT, F.R.C.S.ENG., F.R.F.P.S.GLAS.,

HONORARY SURGEON, NORTH RIDING INFIRMARY, MIDDLESBROUGH.

The term "*post-partum* haemorrhage" is one which, in its accepted clinical significance, is incapable of exact definition. Its meaning is conventional, and may be described with fair accuracy as an abnormally severe haemorrhage from the parturient canal occurring within twenty-four hours after the birth of the child.

The source assigned indicates the idea of the purely obstetric nature of the haemorrhage. The time limit has been arbitrarily fixed for convenience. The measure of quantity is unavoidably vague. Practically, it is the opinion of the medical attendant in the particular case that the haemorrhage is sufficiently severe to call for measures for its arrest, and to merit the term "*post-partum* haemorrhage."

Cases of *post-partum* haemorrhage are usually classified in three groups according to their causes, which in turn indicate the appropriate lines of treatment:

1. Laceration of the parturient canal.
2. Retention of the placenta (partial or complete) within the uterus.
3. Inadequate shrinkage of the uterus.

Obviously any two or all three of these conditions may coexist. In all of these cases, as indeed in all cases of haemorrhage in whatever situation, treatment has three successive objects, namely:

1. The immediate arrest of the haemorrhage.
2. The immediately succeeding maintenance of this arrest.
3. The permanent closure of the bleeding vessels.

The general principles of treatment are the same for all cases. The particular means employed for the first and second objects may properly depend to some extent on the severity of the haemorrhage in the particular case, and the same means can promote both objects. The third object is attained by purely natural means, namely, the formation and growth of new tissue.

Post-partum Haemorrhage due to Laceration of the Parturient Canal.

Its nature is proved by seeing or feeling the laceration or lacerations. Failing this, it may be confidently inferred from the presence of its characteristic feature, namely, persistence of the haemorrhage, despite firm uterine contraction, more especially after complete expulsion of the placenta. Treatment consists in suturing or plugging the lacerations.

Post-partum Haemorrhage from Retention in the Uterus of the Placenta.

When due to retention of the placenta in whole or in part, the haemorrhage takes place from the open blood channels in the uterine wall and in the placenta (when the latter is only partially separated). The haemorrhage here implies placental separation in some degree, for while the placenta is yet entirely attached to the uterine wall (that is, while as yet no separation whatever has occurred) the blood channels are intact, and therefore no haemorrhage can occur. Under normal conditions the same forces—contraction and retraction of the uterus—simultaneously cause separation of the placenta and closure (by compression) of the opened blood channels in the uterine wall. This sealing effect is maintained until clotting and organization perpetuate it.

With the commencement of placental separation the possibility of *post-partum* haemorrhage begins, and if at any time thereafter and before permanent haemostasis is secured shrinkage of the uterus fail and flaccidity occur, then the temporary sealing of the torn blood channels is liable to become undone and consequent haemorrhage to set in. Obviously, then, the later in the process of placental separation flaccidity of the uterus occurs the larger is the number of blood channels thus opened, and *pro tanto* the severer is the haemorrhage likely to be. Indeed,

the most serious and immediately dangerous cases of *post-partum* haemorrhage are to be found amongst those in which haemorrhage begins after the placenta has been delivered.

The two ready means of resolving doubt as to whether any placental tissue has been retained are inspection of the placenta delivered and palpation of the uterine interior.

In *post-partum* haemorrhage from retained placenta the essentials of treatment are two: (1) to empty the uterus—that is, to remove whatever part of the placenta is still within its cavity, and (2) to promote uterine contraction. Should haemorrhage continue despite complete removal of the placenta the case automatically passes into the next class, and is to be treated accordingly.

Post-partum Haemorrhage from Uterine Flaccidity after Expulsion of the Placenta.

Severe degrees of this form the more immediate subject of this paper. Different terms (for example, atony) have been used to denote the condition of the uterine wall. It matters comparatively little what terms are used provided that one has a clear mental picture of the essential feature, namely, an absence (more or less complete) of the normal shrinkage of the uterus, which shrinkage is due to contraction and retraction of the muscle fibres in the uterine walls.

Where *post-partum* haemorrhage of this kind is a continuance of a haemorrhage preceding expulsion of the placenta the medical attendant is in a favourable position to check it, because, engaged in the delivery of the placenta, he is bound to be aware of its existence at the earliest stage.

Matters are very different where haemorrhage begins after expulsion of the placenta. Here one meets with the gravest cases of *post-partum* haemorrhage. Probably no haemorrhage of equal severity occurs in circumstances so little likely to attract the immediate notice of either the medical attendant or the patient. Here is no dramatic violence compelling attention as in the case of surface wounds. There is here no pain to enforce complaint, such as accompanies the blanching haemorrhage of ruptured tubal pregnancy. Unlike a haematemesis, this haemorrhage, occurring under bedclothes, is unseen. The patient, exhausted by her confinement, is at first aware only of an increase in the flow of warm discharge, which she has no reason to suppose is not quite usual and natural. She soon feels faint but not surprised, and almost immediately is beyond power of speech. Such are the cases in which the medical attendant, having delivered the placenta, felt the uterus to be contracted, and finished his bedside duties, inspects the child, washes his hands, and, returning to his patient's side, is staggered to find her blanched, breathing almost imperceptibly, scarcely conscious, dying.

It is when faced with such a situation as this that one appreciates the immense advantage of having at instant command a simple, direct, efficacious, and easily applied line of treatment which has been thought out by oneself beforehand. It may be said that this is so self-evident and is so universally realized as to call for no remark. Experience in cases seen in consultation has proved the contrary. Conversation with different medical men has confirmed this conclusion. A reference to various textbooks in the English language suggests that their authors have succeeded in describing an encyclopaedic list of the different means that have at any time been used to check *post-partum* haemorrhage rather than in giving a clear lead in the selection and precise application of the best.

This paper has been written in order to emphasize the importance of a pre-determined line of treatment, to describe and discuss a method used by the writer for a number of years with good results, and to urge the great value of a particular measure in that treatment—namely, immediate elevation of the bleeding surface.

The morbid condition is a mixed haemorrhage, of which the immediate cause is uterine flaccidity, and the predisposing causes are any and all conditions that make for uterine flaccidity. That the haemorrhage is in part arterial is indicated by the immediate effect of compression of the abdominal aorta. That it is in part venous is indicated by its colour. The arterial haemorrhage is by onward flow from the curling arteries. The venous

haemorrhage is by regurgitation through the uterine veins, facilitated by the absence of valves from them and from the veins that they feed.

Uterine flaccidity connotes corresponding inadequacy in the mechanical closure by muscular compression of the blood channels traversing the uterine wall at the placental site. It is almost certainly not the only causal factor in every case, but in every case it is to be regarded as the dominant one, and the only one to which attention need be primarily given. Where adequate retraction and contraction exist no *post-partum* haemorrhage occurs.

The conditions predisposing to uterine flaccidity fall into two main groups which obviously are not mutually exclusive, namely:

1. *Conditions existing before labour, and facilitating uterine exhaustion*, including, besides any condition of impaired health, what one can at present only label as "idiosyncrasy," exemplified by those women who, despite reasonably good health and easy labours, suffer from *post-partum* haemorrhage in confinement after confinement. Such a condition cannot be forecast in a first confinement, and need never be overlooked in a subsequent one.

2. *Conditions occurring during labour, and producing uterine exhaustion*—a group practically equivalent to unduly prolonged and unduly precipitate delivery—for example, rapid delivery by forceps after a tedious second stage with consequent failure of pains. Even here the risk of *post-partum* haemorrhage is much diminished by leaving the placenta alone—not seeking by manual compression of the uterus to separate and expel it immediately.

Circumstances Governing Choice of Treatment.

Of these the first is the fact that the haemorrhage is severe, threatening life. Hence the measures chosen should be of prompt applicability and of immediate effect. They should be in action within a few seconds. The other circumstances are chiefly domestic. The majority of confinements take place in cottage homes (often lacking conveniences) where assistance is relatively slight and often unskilled. Here measures of treatment which are and ought to be matters of course in a lying-in hospital are out of the question. The *essentials* of treatment must therefore be independent of all but the most primitive accessories. The mechanism must be personal to the medical attendant. In fine it consists of his head and his hands.

In applying these considerations it is well to regard the problem not as peculiarly an obstetric one, but substantially as a problem in first aid to the wounded, the approximate but not the precise seat of the wound being known. The first object of treatment is the immediate arrest of haemorrhage. Precisely the same principles apply, precisely the same kind of measures should be employed, as in the case of a severely bleeding wound of a limb, namely:

1. Pressure—(a) Proximal to the bleeding area.
(b) Local—at the bleeding area.
2. Elevation of the bleeding area.

The facility with which these measures can be applied depends to some extent on the assistance at command. Single-handed one can apply pressure. With one assistant it is possible to carry out both lines of treatment simultaneously. But the help of a second assistant greatly facilitates matters. There must be few occasions on which this assistance is not available.

The procedure here advocated may be described in connexion with an imaginary case. The patient's appearance suggests the condition present. The bedclothes are at once thrown off and the quantity of blood seen practically clinches the diagnosis. With one hand the abdominal aorta is compressed—an easy thing to do through the lax abdominal wall, and one which should not require more than three seconds. Meanwhile the nurse is called to the bedside and further assistance, if not in the room, is shouted for. The other hand separates the thighs and is then passed into the vagina. The cervix is felt and grasped with moderate firmness in order to steady it and so help the other hand in its next manoeuvre. As soon as this is done the abdominal hand, leaving the aorta for the moment, "gathers" the relaxed and blood-filled uterus in its hollow, squeezes it, and presses it down in an ante-flexed position against the vaginal hand, which meanwhile has been shut and moved into the anterior vaginal fornix.

The anterior and posterior uterine walls are now pressed against each other by the two hands. At the same time some pressure, if thought desirable, is made on the aorta by the back of the wrist of the abdominal hand.

While this is being done an assistant places a pillow between the patient's head and the top of the bed to act as a buffer. As soon as the uterus is gripped between the attendant's hands the nurse lifts up the patient's pelvis as high as possible—practically to an angle of 60 or 70 degrees with the bed—that is, the patient is placed in the Trendelenburg position. The necessary counter pressure is given by the resistance of the bed-head to the head of the patient who now rests on the back of her shoulders, neck, and head. All the above manoeuvres need not occupy more than thirty or forty seconds.

Meanwhile the additional help, which by this time has arrived, prepares whatever is necessary and available to maintain the Trendelenburg position in order to relieve and set free the nurse. Suitable mechanical supports are pillows, etc., a partly inverted chair, and a towel or sheet as a sling from the bed-top. Others will readily suggest themselves.

The above measures will, with practical certainty, secure the complete arrest of haemorrhage as soon as they are in operation. No other *local* treatment is attempted. But if the patient's condition suggest danger from low blood pressure, then her arms and legs are raised to the vertical and held there by the assistants.

When the uterus is felt to be firmly contracted (and on no account before this is so) the vaginal hand is withdrawn, and is then available for other purposes, a wet pad being applied to the vulva as the hand is withdrawn.

As soon as uterine contraction and the patient's general condition are satisfactory the pelvis is lowered to an angle of about 30 degrees and the abdominal hand removed, being returned from time to time to observe the condition of the uterus. A binder is tightly applied. The patient is kept in this elevated position for as long as seems desirable—never less than several hours—her legs being supported in a horizontal position. Whatever additional measures may be thought desirable for the maintenance of haemostasis and uterine contraction are applied, and suitable arrangements are made for the patient's general comfort.

REMARKS ON THE FOREGOING.

Proximal Pressure: Compression of Aorta.—The object of this is to check arterial haemorrhage by preventing blood reaching the uterus. It is the first manoeuvre employed because it can be most quickly applied. Since almost the entire arterial blood supply of the uterus reaches it through the terminal branches of the aorta the effect of compression is to prevent this blood reaching the uterus, and *pro tanto* to diminish the haemorrhage. But compression of the aorta can have further effects. The uterus, being relaxed and containing much blood, extends a considerable distance up into the abdomen, lying in front of the aorta. Hence pressure on the aorta will be exerted through the uterine walls. The effects of this on the uterus will be to stimulate it in some degree to contract, to express blood from its interior, and to "block" the placental site should this be in the line of pressure.

As probably much of the haemorrhage is due to regurgitation from the iliac and caval veins it might be thought worth while to use the abdominal hand for simultaneous compression of the aorta and inferior vena cava. No doubt the greatly relaxed abdominal wall and low blood pressure would permit of this being readily enough done. But there are strong reasons against any attempt, for example, the slightly longer time required to get the hand into accurate position, the risk of failing completely to compress the aorta, the certain diversion by regurgitation to the uterine veins of blood returning from the lower limbs.

Local Pressure: Bimanual Compression of the Uterus.—pressure of the anterior and posterior uterine walls against each other between the abdominal hand and the fist in the anterior vaginal fornix—has three objects, namely: (1) To "block" the open blood channels of the placental site by direct pressure, and so to prevent escape of blood from them. (2) To empty the uterus of blood. (3) To stimulate the uterus to contract, and so itself to continue to fulfil the other two objects. The area specially sought to be affected

is the placental site. As the exact position of this is rarely known the entire uterus is compressed in order that the placental site may not be missed. The compression of the placental site is calculated to check *all* haemorrhage, arterial and venous.

Bimanual compression of the uterus, the internal hand being within the uterine cavity, has been advocated as having the following advantages over the above method—the better emptying of the uterus of blood; the more direct compression of the placental site; a greater stimulus to the uterus to contract. Granted that in each method reasonably strong pressure is exerted, then it may be said of the intrauterine method that its first advantage is probably *nil*, at most very slight; its second is *nil*; its third is real, but probably not great. The outstanding disadvantages (they imply the corresponding advantages of the vaginal method) are (1) that a larger area of the flaccid uterine wall will escape compression, and this area may contain the whole or part of the placental site; and (2) the greatly increased risk of intrauterine sepsis, and this in a patient but ill fitted to cope with it. This risk is very great, for the urgency of the case forbids time being spent in any attempt at surgical cleanliness of the hand immediately before its introduction.

Of the two methods, the intrauterine one has slight advantages, serious disadvantages. The balance of value is obvious.

Elevation of the Bleeding Area.

This is of the first importance on account of its efficacy, simplicity, and facility. The more nearly the patient's inverted trunk is to the vertical the more effective is this haemostatic. The effects of this position are that venous haemorrhage by regurgitation is rendered practically impossible, whilst arterial bleeding is greatly diminished. Indeed, where much blood has already been lost, and consequently the heart's action is feeble and the blood pressure low, it is probable that little, if any, arterial haemorrhage would occur even were no other treatment resorted to.

But further important effects follow. Elevation of the pelvis not only automatically lessens or arrests bleeding, it also by gravity drives the unshed venous blood back to the heart and facilitates the flow of blood to the brain, in both of these ways stimulating circulation and respiration at precisely the time when this is most urgently needed. Nay, further, should the patient's condition seem desperate despite these measures, it is enough in addition to have the four limbs held vertically up to secure that practically all the blood in the body is (anatomically) above the level of the navel. If this cannot secure enough blood nourishment to the vital centres there is nothing that can do so short of the introduction of fluid from without. The elevated position recommended greatly facilitates the rapid introduction and retention of such fluid—for example, enemata of hot saline solution.

The degree of elevation here advocated may suggest a risk of air embolism from "adspiration" into the uterus and thence to the uterine veins on withdrawal of the vaginal hand. Whatever this risk might be it is counteracted by two precautions, namely, (1) uterine contraction; the hand is not to be withdrawn from the vagina until this natural preventive is in active operation; while it is so in operation air may enter the vagina, but cannot enter the uterus; (2) closing the vaginal orifice with a wet pad on the vulva as the hand is withdrawn. This prevents a rush of air into the vagina.

CONCLUSION.

In the foregoing remarks I have sought to emphasize the great importance of high elevation of the pelvis as a *primary* measure because I know of no contra-indication to its use; because it does not interfere with any other appropriate measure of treatment; because it promptly, simply, and effectively deals with the immediate cause of great danger; and because it continues to act in the promotion of the patient's subsequent recovery. It is almost incredible that there have not been many men who on many occasions have used to check *post-partum* haemorrhage a measure so simple, easy and effective, resting on a principle so familiar as the law of gravity, and taught and employed time out of mind in connexion with wounds of the extremities. I have there-

fore been surprised to find that of the many obstetricians, general and special, to whom I have mentioned the matter in conversation, every one found the suggestion a novelty. I have looked up a number of English and American textbooks on midwifery. In none of these did I find any mention of this measure of treatment. It is true that elevation of the pelvis by raising the foot of the bed after arrest of haemorrhage has been secured is mentioned. But the employment of the high position as a primary measure rests on a quite different conception from the other. From that the elevation advocated in this paper differs in its object, its degree, and in the time and mode of its application. There would thus appear to be some ground for thinking that familiarity with the use of this measure is not as wide as it might be. It is for this reason that I have sought to call special attention to its value.

Of the whole line of immediate treatment advocated above, the essential value lies in these facts:—it is simple in application; it is prompt and effective in action; and it is entirely personal in its mechanism; that is, it is independent of environment, it needs no "apparatus," it is carried out as easily in a hut as in a hospital.

CAESAREAN SECTION IN A PITMAN'S COTTAGE.

By R. GORDON BELL, F.R.C.S. EDIN.,

SUNDERLAND; FORMERLY DEMONSTRATOR AND ASSISTANT TO THE PROFESSOR OF ANATOMY, UNIVERSITY OF GLASGOW.

On September 7th, 1915, I was asked by Dr. Anderson, of Seaham Colliery, to see a patient who had been fifteen hours in labour at full time without any signs of the head engaging in the pelvis. There was a history of two previous labours which had ended in the sacrifice of the child.

Measurements showed the conjugate diameter to be just over 3 in., and the promontory of the sacrum was within rather easy reach by digital examination.

As the parents were very unwilling to risk the loss of another child, and as the conditions demanded either craniotomy or Caesarean section, I elected to do the latter.

There was one clean room available; the removal of superfluous ornaments, hangings, and furniture was followed by a cleansing with a damp cloth and the spraying of the walls, floor, and ceiling with formalin; the room was then closed for two hours; this gave me the nearest approach possible in the circumstances to the surroundings of an operating-room. Meantime detailed preparations were made for the sterilizing of all necessary articles. Two drums of sterile dressings and masks can always be at hand, but in addition I transported a small Cathcart sterilizer, which was placed on a gas ring, and towels and gowns were steamed, sterilized, and dried in this. Instruments and gloves were easily dealt with in the small portable sterilizer contained in most operating bags. The skin of the patient was prepared in the usual way, and after being thoroughly dried, was coated with a 2½ per cent. solution of iodine in spirit and water.

Preparations were all completed within three hours from the time the message was received; the patient's condition was good, the pains strong and frequent, and re-examination revealed not the slightest progress.

The details of the operation scarcely differed from the description in Berkeley and Bouney's *Gynaecological Operations*, and included the use of boiled silk throughout except for skin sutures. A variation from their technique was, I think, a slight improvement for the prevention of haemorrhage from the cut uterine surfaces. A large vulcanite pessary was boiled along with the instruments, moulded to the shape of a cartouche, fixed in this position by tying with silk while it was still plastic, and re-hardened in cold, sterile water. By pressing firmly on one side of this myself, and the assistant doing the same on the other side, we had no difficulty in avoiding bleeding. I believe this method was suggested years ago by Professor Murdoch Cameron of Glasgow.

The child, a girl weighing 8 lb., was easily removed and breathed at once. It lacked the usual frontal and occipital moulding of the ordinary baby, and therefore looked more

like a child a month old. The mother made an uninterrupted recovery; the pulse never rose above 76, and the temperature was normal throughout, not showing even the ordinary rise when the milk flow was established on the third day.

An examination of the pelvic brim from inside showed the promontory of the sacrum projecting forward and considerably larger and wider than usual. The os was very fully dilated, and there was free drainage by the vagina in the normal way.

I should much have preferred the comfort of a nursing home for this operation, but it was not possible, and I am convinced that many operations involving the transport of the patient by road could quite well be done at home. Except for the air and dust of the ordinary room, one can have all the other essentials of complete asepsis, provided one has a good surgical nurse. But, of course, it is more trouble.

In 1907, at the spring meeting of the Northumberland and Durham Medical Society, I showed a number of major abdominal operations done in private houses, and an interesting discussion took place on the possibility of doing most operations in the homes of patients, and thus relieving the pressure on hospitals.

I was much indebted to Dr. William MacMurray for valuable help, to Dr. Anderson for very efficient anaesthetizing, and to Nurse French for vigilant preparations both before and after the operation.

THE INFLUENCE OF SYPHILIS ON THE CHANCES OF PROGENY.

BY

N. BISHOP HARMAN, M.A., M.B.CANTAB., F.R.C.S. Eng.,
OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL; THE
BELGRAVE HOSPITAL FOR CHILDREN; AND THE WEST
END HOSPITAL FOR NERVOUS DISEASES.

THE effect of syphilis on the child-bearing capability of a woman is well-known, but there are few definite figures that set out this common knowledge in an easily remembered fashion; for this reason the figures presented in this paper may be of interest.

At the annual meeting of the British Medical Association in Aberdeen (1914), I presented to the Ophthalmological Section a paper giving a return of the causes of blindness in eleven hundred children, with special reference to the influence of venereal disease.¹

In the investigation of the case-papers of these 1,100 children I found, in a large number of cases of children whose blindness was the undoubted effect of parental syphilis, that I had investigated the family history—that is to say, the mother of the child had been seen and the history of her married life, so far as its results in the matter of pregnancies and the results of these pregnancies were concerned, had been tabulated. These detailed family histories number 150. In each of these families one or more of the children had been under my care, often for many years, and were undoubted sufferers from congenital or inherited syphilis. Besides the state of blindness due to this cause, either by reason of interstitial keratitis, iritis, or disseminated choroiditis, there were other indubitable signs of syphilis in Hutchinsonian teeth, the characteristic physiognomy, radiating scars at the angles of the mouth, evidence of bone or joint disease, ulceration of the nose or palate, deafness. Whatever may be said for and against the evidential value of the widely-used blood tests for syphilis, there is no doubt in the minds of any one of the certainty of the evidence presented by the finding of these other clinical features. Hutchinsonian teeth alone give certainty; the association of this form of teeth with one or more of these other clinical characters provides a superabundance of certainty. This was the fact with regard to these 150 families; in no less than 68.5 per cent. Hutchinsonian teeth were present in the blind child of the family, and besides the teeth, one, two, or three other symptoms were noted. In those cases where the evidence of the teeth was lacking there were the other symptoms in sufficient number to leave no room for doubt as to the cause of the state of blindness.

Totals ...	150*	390	92	80	229	210

* = 1,001 pregnancies.

Amongst the eleven families to which only one child was born there were four illegitimate unions and the progeny therefrom; all these eleven were blind children and alive at the time of the inquiry.

The column "healthy children" includes all those children reported healthy by their parents or guardians. In the majority of cases it was not possible to examine them, so that the statement of health must be taken with reservations. It also includes those children who had died from accidental causes or from febrile conditions from the age of 3 years and onwards where there was no reason to suspect that the fatal disorder was connected with syphilis.

The column headed "affected by syphilis" includes all those seen by me and ascertained to be the subjects of definite syphilitic conditions. Taking into consideration the statement made regarding those entered as "healthy" it will be seen that any error in the table under-estimates the number of the syphilitic and over-estimates the number of "healthy."

The history of these 150 families set out by themselves would provide a characteristic picture; but for the proper appreciation of this picture it is necessary to set beside it another picture, one giving the family history of an equal number of women who were neither the subjects of syphilis nor the progenitors of syphilitic children. This second picture has been prepared, and the contrast between the two is interesting in the extreme. The standard of comparison provided in this second picture was obtained by an inquiry into the family history of a number of women who were attending the West London Hospital. This hospital has a very large *clientèle*, and the patients are amongst the poorest and most deserving of charity of any attending the great London hospitals. On the average these women were if anything a little poorer than the average of the syphilitic parents whose family histories mainly concern us. The history of 150 women was inquired into; there was no selection of cases, except that where one of known syphilitic history was found she was excluded from the count. But no special measures were taken to ascertain whether or no there was any syphilitic taint. The return obtained from the investigation of the family histories of these women may be taken as a fair average return of family history for the poorest section of the London community.

The comparison of Tables I and II can best be made by means of the familiar device of parallel columns; the

TABLE II.—One Hundred and Fifty Healthy Families not known to be affected with Syphilis.

1	11	10	—	—	1
Totals ...	150*	654	61	17	94

* = 826 pregnancies.

diagram shows such a graphic representation. The difference between the results of the fertilization of these two sets of women is remarkable; 150 syphilitic mothers had no fewer than 1,001 pregnancies, but of these only 390 resulted in presumably healthy children. And it must be remembered that in these cases not every mother began her maternal career as an affected woman; many of the pedigrees show that she was healthy and bore a number of healthy children before the taint affected her; after

that, miscarriages, still-births, and diseased children were born. On the other hand, 150 healthy mothers had 826 pregnancies, and from these there resulted 654 healthy children.

The outcome of the pregnancies of the two classes may be compared further by setting them against each other on the basis of a thousand pregnancies, thus:

TABLE III.—Rates per 1,000.

Parentage.	Healthy Children.	Mis-carriages.	Still-births.	Infant Deaths.	Diseased with Syphilis.
Syphilitic ...	390	92	80	229	210
Healthy ...	791.7	73.8	20.5	113.8	—

Remark may be made on the fact that the syphilitic mothers had about 17 per cent. more pregnancies than the healthy mothers. This may be accounted for in part by the frequency of miscarriages and still-births in the syphilitic. The short intervals between many of these would allow of several ineffective pregnancies within the same time as would be taken for one full pregnancy in a healthy mother. Further, the frequency of these ineffective pregnancies and the many infant deaths would keep the family of the syphilitics down, so that where there is a desire for children the pregnancies would be increased in number.

It is unnecessary to point the moral, the figures speak sufficiently of the influence of parental syphilis on the chances of healthy progeny.

A SPLINT FOR COMPOUND FRACTURE OF THE ANKLE.

By MAJOR M. SINCLAIR, R.A.M.C.

This splint was first applied to a compound dislocation of the right astragalus, but could be used for any compound injury in that region. Astragalectomy had been performed by Captain St. John D. Buxton, R.A.M.C., who asked me to suggest a method of fixation which would allow easy access to the wound.

There were minor injuries to the skin posteriorly, and great oedema due to septic infection of the foot and ankle as far as the knee. The ankle required frequent dressings, and the foot could neither be kept in good position nor quiet, and caused great pain to the patient.

A splint was constructed to fix the foot at a right angle, to immobilize the ankle, and allow ready access for dressings.

The patient was in hospital for three weeks, and was sent home in the splint, which proved so satisfactory for treatment and transport as to make its construction and method of application worth recording.

The splint was made out of the aluminium splinting from the field service fracture box in the following way:

FIG. 1.—A F = 15 in.; F H = 11 in.; H I = 11 in.; I J = 3 in. Total length = 40 in.

A length of aluminium of 40 in. is bent on its edge at F to an angle of 40 degrees, at H to an angle of 130 degrees, and bent on the flat at I to an angle of 45 degrees.

Another length of 40 in. is bent in the same way, having the staples corresponding and on the outside.

These two pieces are riveted at C and F, parallel and 6 in. apart, with 8 in. by $\frac{1}{2}$ in. by $\frac{1}{4}$ in. aluminium.

The transverse bar at F has a staple, K, in the centre, from which the foot is slung. Transverse bars of ribbon aluminium are fixed at B and E, and to these a sheet of perforated zinc 5 in. by 10 in. is laced with wire to form a smooth support for the sole of the foot. From D a strip of ribbon aluminium runs at right angles to F A as far as the point G. Another strip of aluminium ribbon runs from G to the corresponding point on the other half of the splint, and the junctions at G are fixed by riveting.

These supports give the necessary rigidity, prevent the angle at F enlarging owing to the weight of the limb, and the respective supports D G fix the ends of the bandage which keeps the dressings in position. L is an arc of aluminium 4 in. in length with a central staple to which a cord is attached. It is placed in the toe of a sock in which is a small hole for the cord.

The arc L acts as a spreader to prevent crowding together of the toes when the foot is suspended.

FIG. 2.

FIG. 3.

Four loops of cord are fixed at F and I to sling the limb to a modified Balkan by means of weights, cords, and pulleys. A suitable cotton sock is cut obliquely from the heel to the middle of the instep. The arc of aluminium, L, is inserted into the toes of the sock and the cord allowed to pass out through a small hole at the extremity. The foot is cleaned with petrol or ether to remove the grease. The sock is applied dry and its outside painted with a solution of equal parts of Canada balsam in xylol, Venice turpentine, and ether. When dry a layer of cotton-wool is placed between the perforated zinc and the foot, and the two fixed together with a band of adhesive plaster round the dorsum. The cord from the arc L is adjusted until the bars H I are parallel with the bones of the leg. The latter is embedded in a plaster case extending down as far as convenient (about 6 or 7 in.) from the tuberosity of the tibia. The uncovered portion of the leg is supported

with suspensions of elastic webbing or bandage. The foot is now fixed at right angles to the leg.

Figs. 2 and 3 show the splint applied to a patient and slung by four cords, snap hooks, sandbags, and eight pulleys to a modified horizontal bar. This gives the patient free movement in bed and the attendants ready access to the wounds.

BRONCHOPNEUMONIA WITH SECONDARY HAEMORRHAGIC MENINGITIS AND RECOVERY.

By A. GEOFFREY SHERA, B.A., M.B., B.C. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.,

LATE CLINICAL ASSISTANT IN THE MEDICAL DEPARTMENT OF THE
EVELINA HOSPITAL FOR CHILDREN, S.E.; LIEUTENANT, R.A.M.C. (T.C.),
ATTACHED MILITARY HOSPITAL, EASTBOURNE.

In the course of a series of some 14 cases of bronchopneumonia in children, occurring nearly a year ago, the following somewhat remarkable case was encountered—to wit, a mixed meningeal infection with spontaneous recovery. The mixed infection was, so far as was ascertainable, due to Fraenkel's pneumococcus, together with Friedlaender's diplobacillus, the latter in great numerical predominance.

The original investigation was undertaken with a view to confirm or dispel Hutchison's suggestion that a streptococcal strain in bronchopneumonic infection is of grave prognostic import, quite apart from other considerations.

The sputum was obtained by first slightly irritating the pharyngeal wall and so causing a short onset of coughing and production of sputum, a sample of which was obtained on a sterile platinum wire and straightway inoculated on blood-agar, all contact with mouth or fauces being most carefully avoided. Thus the proverbial difficulty of obtaining infantile sputum was overcome.

The particular case in question was one of a series of cases of infantile bronchopneumonia admitted last January to a London infirmary. All but two were under the age of 3 years. A very large proportion of these cases showed the predominance of the pneumobacillus (Friedlaender's) both in smears and in cultures from the sputum.

It is relevant in this connexion to recall the chief morphological and cultural characteristics of these two pneumonic organisms, not for didactic purposes, but as a labour-saving device.

The *Pneumococcus lanceolatus* is Gram-positive, and stains deeply in sputum, often (in these cases) showing chains of two, three, or four pairs, and is encapsulated. As a rule there were series of long chains which showed all transitions from a typical streptococcal arrangement to a gradual separation into diplococci, the morphological explanation of which should prove interesting. On blood-agar the colonies were almost transparent, and very small when found separate, and this was only at the edges.

The pneumobacillus, on the other hand, is Gram-negative. It is also encapsulated, and both forms reveal encapsulation remarkably well in sputum. The colonies resemble knobs of ivory, and a stab culture shows a characteristic "nail-like" form with a process in the substance of the agar; the "head" is a heaped-up mass, densely white. The organism is non-motile. This latter fact, together with morphological considerations, and its presence in sputum, also the absence of intestinal symptoms, enabled one to make sure that one was not dealing with *B. enteritidis* of Gaertner, which has one or two similar characters. It is, for instance, Gram-negative, and produces haemorrhagic lesions, including a single recorded case of "meningitis haemorrhagica," a clinical entity for whose existence this organism is held to be solely responsible, when considering the group it represents.*

The sputum contained other organisms besides these two, such as staphylococci and diphtheroid rods, but these were not of significance in regard to the meningeal symptoms.

CASE.

A boy, aged 18 months, was admitted on December 29th, 1914, with marked meningeal and chest signs and symptoms.

History and Condition on Admission.

Save for the fact that he had not been ill before two days earlier, and that he had been fed on cow's milk, no history was

* Muir and Ritchie: *Manual of Bacteriology*, 1913, p. 383.

forthcoming. On admission the temperature was 97°, and, curiously enough, remained subnormal throughout, possibly indicative of a severe haemia, and so of a bulbar toxæmia, with paralysis of the heat-regulating centres. The respirations were 42, the pulse 112.

Central Nervous System.—The meningeal signs and symptoms were as follows: There was head retraction to a marked degree, *tache cérébrale* and Kernig's sign, with rigidity of the legs, the right leg being flexed more than the left; he screamed intermittently but frequently in a typical manner. The knee-jerks were increased, and the plantar response was (probably because he had not learnt to walk) doubly extensor, but notably brisk. He had a left internal strabismus. He appeared to be thin, and showed loss of flesh whilst under observation. He was extremely peevish and mentally irritable. The three highest mental faculties were all impaired—to wit, attention, judgement, and self-control. No convulsions occurred.

Respiratory System.—The child had pneumonic breathing, patchy dullness at the lower angles of the scapulae, below the left clavicle, and markedly at the bases, with fine crepitations.

Sputum.—Examination of the sputum showed a large number of pneumobacilli, strepto-diplococci (adherent pneumococci in chains in all stages of separation up to twenty pairs or more), and ordinary detached pneumococci.

Lumbar puncture yielded about 10 c.cm. of turbid fluid, with a negative haemoglobin spectrum. This was centrifugized, and also inoculated on blood-agar directly. Cultures of pneumobacilli and pneumococci were found alone. The former enormously predominated.

After-History.

On the seventh day of illness (January 3rd, 1915), that is, five days later, the condition of the child had markedly improved. He was much quieter, and screamed only occasionally during the day, but he was still restless at night, crying out often. The following mixture was found to be effectually sedative: Pot. brom. gr. iv, tr. bellad. m. iij, glycerine m. x, aquam ad ʒi; sig. ʒi nocte p.r.n. Head retraction and squint were still present, as also was Kernig's sign. The pneumonic condition was much the same as before, but pneumonic breathing, instead of being continuous, only occurred if the child were disturbed. The pulse was 85 and the respirations 30. Eight days later, on the thirteenth day of illness (January 11th, 1915), lumbar puncture was again performed and the fluid was thickly haemorrhagic, and cultures showed abundant colonies of Friedländer's bacillus and a few pneumococcal colonies also.

The condition of the child improved after this. Only a few rhonchi were noted in the chest, and pneumonic breathing had ceased. Cerebral scream had also vanished, but the child was irritable. Kernig's sign could not be obtained; there was no squint, and much less head retraction.

On January 15th, 1915—that is, the nineteenth day of illness (four days later)—the child was sitting up and taking an interest in his surroundings, to all intents and purposes quite well, although thin and wan to the eye. The lungs were now clear.

Lumbar puncture, cultivated on blood-agar, showed pure Friedländer's bacilli. The fluid thus obtained was still haemorrhagic.

On January 18th—that is, twenty-second day of illness—a final lumbar puncture was performed. The fluid was tinged with blood, but quite sterile on inoculation.

The child was normal in behaviour, slept and fed well, and was not in the least fretful. All nervous signs had disappeared, including squint. A second examination of the sputum showed staphylococci, pneumococci, also pneumo-streptococcal forms, and notably enormous numbers of pneumobacilli in smears.

The question arises whether what was taken for pneumobacilli were not in reality *B. enteritidis* of Gaertner, since this organism has been known to cause a meningitis characterized by haemorrhagic lesions likewise. Against this is the fact that this case showed no intestinal symptoms, and that 13 other cases of bronchopneumonia in the same ward showed no intestinal symptoms, and all showed in the sputum predominance of pneumobacilli, which were morphologically pneumobacilli and had the pathognomonic "nail-like" culture form. Unfortunately, lack of apparatus prevented me testing the indol and lactose reactions, but I can assert that the organism was non-motile. Moreover, I venture the opinion that clinical guidance was both confirmatory and reliable in this case. So far as I can ascertain, *B. enteritidis* has not been recorded in the etiology of bronchopneumonia. I therefore ruled out *B. enteritidis*.

Some writers identify the pneumobacillus with *B. lactis aërogenes*, which occurs most commonly in sour milk. That this may be true I do not dispute theoretically, but even so this is irrelevant to the essential substance of my thesis. Possibly it may be argued that this series of cases is in favour of this more improbable contention, since children in poor circumstances at such a tender age and with such careless mothers as some of them have, may well receive sour milk for food. But it seems strange that a normal inhabitant of the intestine should, for no

particular reason, suddenly migrate to the meninges to assume a pathogenic rôle, having previously attacked the bronchial mucous membrane. The total absence of intestinal disorder also contravenes this particular explanation. It is therefore not unnatural to conclude that one was dealing with a strain of true Friedländer bacillus as originally contended.

Critics may rightly ask why splenic and blood cultures were not made. The answer is that the particular case occurred in an investigation undertaken for a totally different purpose, and that it was not until I came across the notes of the case in revising the others that it occurred to me to record it; then the opportunity for making such cultures had gone, the child having disappeared.

I have noted the case for a dual purpose. Firstly, to demonstrate the prognostic value and manner of sputum examination in children with bronchopneumonia, and secondly, in the hope that a clinical variety of meningitis, with a favourable prognosis, may be established—and this is submitted as a desirable objective from the medical, from the maternal, and especially from the national point of view, in face of the heavy toll of childhood which meningitis in all its forms exacts to-day, when more than ever do we require to conserve a healthy childhood.

TRAUMATIC RUPTURE OF THE SPLEEN: SPLENECTOMY: RECOVERY.

BY

WALTER H. CAM, M.A., M.B., B.C. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.,

ASSISTANT SURGEON, SAVERNAKE HOSPITAL, WILTS.

A HEALTHY married woman aged 31, the mother of four healthy children, spent the first twenty-one years of her life in South Africa and never had a day's illness. Since living in this country she has from time to time suffered from a fairly severe degree of anaemia, but has never needed a doctor except for her confinements.

On August 6th, at 3 p.m., she found a nail projecting through the sole of her boot. She stood up on a kitchen chair to reach a set of boot lasts and a hammer from a shelf (Fig. 1). The chair tilted forwards, the hind legs

FIG. 1.

FIG. 2.

FIG. 3.

leaving the ground, her feet slipped. She fell forwards, striking her epigastrium on the edge of the chair-back (Fig. 2). Her weight then carried the hind legs of the chair to the ground, and she received a second and more severe blow as the hind legs regained the ground (Fig. 3). She continued with the job in hand, picked up the boot lasts and hammer which had slipped from her grasp, and having satisfactorily knocked down the nail in her boot, again stood on the chair, and replaced the boot lasts on the shelf. This accomplished she felt faint and sick, walked upstairs to her bedroom, and lay down.

One of her children was then dispatched to me. Unfortunately I was out, but on my return at 6 p.m. I went to her house and found a colleague had in the meantime been sent for and had, about twenty minutes previous to my arrival, given morphine gr. $\frac{1}{4}$ hypodermically. The patient was lying in bed blanched and nearly pulseless, with the

knees slightly flexed and her hands under the back of her head, resting on the pillow. The pulse was 130, the temperature 98° F., and the respirations 32. The pain, which had been very severe, was easier; she had not vomited, but felt sick, and complained of a desire to micturate, which she had been unable to satisfy.

There was no visible sign of injury, such as a graze or bruise, but the whole abdomen was rigid to palpation. The point of maximum tenderness appeared to be to the left of the mid-line and in the left iliac fossa, but her condition was too grave to justify questioning. To percussion the whole of the left flank seemed duller than the right, but no definite shifting dullness could be found. The liver dullness was normal. The catamenia were regular and no period had been missed. I ordered her immediate removal to hospital.

At 7 p.m. she was anaesthetized with open ether. Examination then revealed definite dullness in the left side of the abdomen, which did not shift. A catheter was passed and about 8 oz. of pale and normal-looking urine withdrawn. The only possible diagnosis was severe internal haemorrhage, and the spleen appeared the most probable source in view of the fact that the urine was normal. It was impossible to exclude injury to the gastro-intestinal tract in addition.

Operation.

A median incision was made below the umbilicus and free blood could be seen through the peritoneum before this membrane had been incised. The incision was then extended upwards. The peritoneal cavity was full of blood and blood clot. On commencing to remove the latter, bright fresh blood welled up extremely profusely. Examination revealed to the touch a tear in the visceral surface of the spleen. The bleeding appeared to be controlled when the splenic artery and vein were compressed. This was effected with the left hand whilst the spleen was brought into view with the right. The tear was then seen to extend through the hilum involving the point of entry of the vessels.

As time was of the utmost importance, no effort was made to isolate the individual vessels. A pedicle needle was passed through the extreme tail of the pancreas and one ligature made to include the whole vascular pedicle of the spleen, which was then removed. The peritoneal cavity was cleared of blood and clots and then flushed with normal saline at a temperature of 112° F. The incision was closed in layers, and as much saline left in the cavity as could be retained. At the conclusion of the operation the colour was better, the pulse 120 but much fuller, and the respirations 36.

After-Treatment.

The patient was put in the low Trendelenburg position, and rectal saline injections were immediately started. To the first saline injection of 2 pints, brandy 1 oz. and aspirin gr. xv were added. The instructions were to repeat the saline injections every two hours as long as the patient could retain them, and that the bed was to be put flat at the expiration of four hours. The following morning the head of the bed was raised on high blocks.

The patient made an uneventful recovery. The temperature rose to 100° in the first twenty-four hours, but thenceforward remained normal or subnormal. No external bruising ever developed, nor was there any injury to ribs.

REMARKS.

The main interest in the case appears to lie in the fact that it is possible to sustain such a severe injury from a comparatively trivial accident. The patient is an averagely covered woman, weighing 8 st. 7 lb., and stands 5 ft. 2½ in. Macroscopically the spleen appeared healthy.

I am indebted to Dr. Penny for giving the anaesthetic and to Dr. W. B. Maurice for assisting me at the operation.

The accompanying sketches are intended to illustrate precisely how the injury occurred; and Dr. H. M. Turnbull, Director of the Pathological Institute, London Hospital, who kindly examined the spleen for me, reports that with the exception that it was very anaemic, it was otherwise normal in every way.

TRAUMATIC RUPTURE OF SPLEEN.

WITH A FEW NOTES ON THE BLOOD.

BY

CAPTAIN E. H. JONES, M.B., B.S., R.A.M.C.

The patient whose case is here related was admitted to the Preston Royal Infirmary, October 31st, 1912, under the late Dr. Garner.

T. W., a boy aged 10, had fallen a distance of 20 ft., coming in contact with a tree stump. He walked 100 yards and then fainted. He was admitted to hospital the same evening, with signs of intra-abdominal injury.

Operation.

On opening the abdomen by the high rectus incision I found that the peritoneal cavity contained much free blood, the source of which was found to be the spleen, which was almost completely severed. The organ was removed through a transverse incision, commencing at the apex of the exploratory opening, and the abdomen closed hurriedly.

After-History.

For seven days progress was uneventful. On November 7th, 1912, the temperature shot up to 104° and reached 105° on the next four days. The patient had definite bronchopneumonia, the temperature returning to normal by lysis by November 19th, 1912.

He was discharged on December 18th, 1912.

I saw the boy on November 14th, 1915 (three years after the operation), and he was quite healthy, doing half-time at the mill.

Blood Counts.

On November 3rd, 1912 (three days after the operation), the blood count was—

Red cells	3,500,000
White cells	15,600
Polymorphonuclears	36 per cent.
Mononuclears	64 per cent.

Following the bronchopneumonia the blood count was—

Red cells	3,500,000
White cells	21,200
Polymorphonuclears	58 per cent.
Mononuclears	42 per cent.

On December 4th, 1912, the blood count was—

Red cells	3,000,000
White cells	11,000
Polymorphonuclears	68 per cent.
Mononuclears	28 per cent.
Eosinophiles	4 per cent.

A year later Dr. Leigh kindly examined his blood for me, and found mononuclears rising in percentage and eosinophiles up to 6 per cent.

On December 14th, 1915, Dr. Tindall, the honorary pathologist to the Preston Royal Infirmary, made a final count, which was as follows:

Red cells	3,200,000
White cells	6,900
Polymorphonuclears	56 per cent.
Mononuclears	44 per cent.

A case Dr. Collinson operated on during the same period, a lad of 19, showed lymphocytosis, which persisted for at least a year, without the return of a higher polymorphonuclear count such as accompanied the bronchopneumonia in my case. Dr. Collinson's case showed an eosinophilia of 12 per cent. twelve months after the operation. This patient is now serving with the colours.

The cases are interesting as showing (1) the original leucocytosis, (2) a relative lymphocytosis of some duration, (3) the transient eosinophilia twelve months after removal of the organ, (4) the absence of any adverse effect following removal of the spleen.

A CASE OF PROBABLE SPONTANEOUS RUPTURE OF THE SPLEEN.

By W. B. OGILVIE, LIEUTENANT-COLONEL I.M.S.,
SUPERINTENDENT, DELHI GAOL.

It is recognized that this case is not a well proved one, but such cases are of so much deep interest to those working in tropical countries that it is thought worth while to record it, incomplete though it is.

Prisoner, male, aged 28, had been in gaol for three months, during which time he had never been in hospital, and his weight had remained steady. On a Sunday he did none of his ordinary work—paper making—but washed his clothes and

bathed, according to the usual routine. On the Monday he ate his full morning meal. He then reported sick, and was detained in hospital. He complained of fever, chill, and cough during the previous night; his temperature was 99.4°. He did not complain of any discomfort in the abdomen, nor did he admit any fall or blow. Careful inquiry failed to elicit any history of a fall or blow. On admission the spleen was enlarged. In the evening his temperature was 102°. He ate the greater part of his evening meal, and complained of nothing beyond the fever. About 10 p.m. he vomited twice or thrice. At midnight he became suddenly collapsed, and died at 1.20 a.m. on the Tuesday.

Post-mortem Examination.—The body was well nourished; rigor mortis was present; there were no marks of violence. The examination was held fifteen hours after death; the body was quite fresh, and showed no signs of commencing decay. The weather was cold and dry. All the tissues were anaemic to a degree. The abdominal cavity was full of clotted blood and clear serum. The spleen was enlarged to twice the normal size, and looked black. On its anterior surface was a tear about 2 in. long. On removing the spleen, the capsule was seen to be distended with firmly clotted blood. The spleen itself was anaemic, the colour was the "light red" of the paint-box, and the substance was almost diffuent—about the consistency of thick porridge. The other organs were normal.

What apparently negatives the possibility of a blow having been received before admission to hospital, and rupture of the spleen thereby, is the steady rise of temperature. Had the spleen been ruptured by a blow there would probably have been shock, and almost certainly no rise of temperature; the internal haemorrhage would have kept the temperature down.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ICHTHYOL IN ERYSIPELAS.

A MAN was admitted with a large suppurating wound on the inner side of the arm, with some redness and swelling around the wound. The temperature rose next day to 104° and then to 105°. The usual signs of erysipelas were present, the redness and swelling extending below the elbow. I ordered the arm to be painted every twelve hours with ichthyol and glycerine equal parts, and covered with oil-silk, and gave him a mixture containing large doses (2 drachms every four hours) of liq. hydrargyri perchloridi. In forty-eight hours the temperature was normal, and all the local symptoms of erysipelas had disappeared; the wound was then dressed with ordinary hypertonic saline solution.

In another case, of a man sent from the trenches with both arms covered with boils, local treatment by ichthyol and glycerine had equally good results.

HELEN SEXTON, M.B., Ch.B.

Médecin Chef, Hôpital Australien, Paris.

RELAPSING BERI-BERI.

THAT beri-beri is due to the deficiency or absence of substances called vitamins; that polished rice is one of the common food substances deficient in vitamins; and that beri-beri is found practically only in rice-eaters—these are the commonly accepted views about the etiology of this interesting ailment, and it may therefore be well to record any definite cases where the disease was clearly not due to rice eating or, indeed, to any obvious want of vitamin substances. The patient, aged about 28 years, was a soldier on sick leave. He contracted beri-beri in India. His was the regulation army diet—meat, vegetables, milk, bread, butter, tea, coffee. On a rare occasion he would take a bit of rice or sago pudding, but at no time of his life was he ever on an exclusive or continuous rice dietary. He had exhibited the usual symptoms—multiple peripheral neuritis, some paralysis and some anaesthesia, very considerable weakness, cardiac dilatation, and oedema of the legs. Under treatment for some months in bed he improved, but signs of cardiac dilatation with a definite bruit still remained. Oedema of the lower extremities was intermittent. He was liable to relapses of the condition whenever he fell into ill health from any cause. These were accompanied by hyperaesthesia of the muscles and of the nerve trunks. During the periods of remission no physical sign of the disease could be seen, except the evidence of cardiac dilatation.

The usual cardiac tonics, as iron and digitalis, appear useful for the heart trouble, but nothing seems to have any specific effect on the beri-beri.

J. C. McWALTER, M.D., D.P.H., R.A.M.C.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

THE LORD DERBY WAR HOSPITAL, WARRINGTON.

A CASE OF SUDDEN HEART FAILURE UNDER ANAESTHESIA: DIRECT MASSAGE OF HEART: RECOVERY.

(By GERALD SICHEL, F.R.C.S., Captain R.A.M.C.)

PRIVATE —, aged 22, was admitted on September 29th, 1915, suffering from a severe gunshot wound of the left hand, received in France on September 26th. A rifle bullet had struck the middle finger, almost completely severing it; the wound was very septic.

He was treated with hypertonic saline baths, and syringing with hydrogen peroxide, and the wound cleaned up considerably. As it was considered necessary to amputate the finger he was, on October 4th, given a general anaesthetic—a mixture of chloroform (two parts) with ether (three parts), and alternately pure ether on an open gauze mask. He was taking the anaesthetic quite well, and was wheeled from the anaesthetizing room into the operation theatre.

He was lifted on to the operation table, when he suddenly became ghastly white, sweated profusely, and the pupils became widely dilated. Breathing continued slow and regular, but rather shallow. No pulse or cardiac impulse could be felt, or heart sounds heard. An incision a little to the left of the middle line was rapidly made into the upper part of the abdomen, and meanwhile hypodermic injections of strychnine and brandy were given, and a cloth wrung out of boiling water applied to the precordium.

The right hand was inserted into the abdomen, and a flabby mass, supposed to be the heart, seized through the diaphragm, and energetically and rhythmically squeezed. In a short time the flabby mass suddenly became hard—like a cricket ball—in the hand, and firm, regular, but slow contraction commenced. After a little these firm contractions became tremulous and threatened to cease, but on squeezing, again became firm and regular; this routine was carried out several times, and at last a regular heart-beat and regular pulse were established. The patient began to strain and vomit, so that there was some difficulty in sewing up the abdominal wound. In about twenty minutes he was taken back to the ward, where a rectal saline injection was administered.

In the evening he suffered from considerable pain in the abdomen and chest, which was allayed by a hypodermic injection of morphine. He made a good recovery, and as it was deemed unwise to give him a further anaesthetic the injured finger was eventually amputated by means of strangulation, with a piece of indiarubber tubing.

Remarks.

1. The man's general vitality was probably considerably lowered from septic absorption.
2. The movement of lifting him from the stretcher on to the table appears to have been the deciding factor in the cardiac failure.
3. The anaesthetic was chiefly ether, the amount of chloroform being very small.
4. The subsequent pain was probably due to bruising of the diaphragm, and perhaps the heart.
5. I think the hypodermic injections of strychnine were of use once the heart's action was re-established, although obviously they could have been of no good whilst the circulation was stagnant.

My thanks are due to Dr. Garner and Mr. Stone, R.A.M.C., for efficient help at the time of the emergency. Dr. Manson was responsible for the subsequent treatment of the patient.

Reports of Societies.

TREATMENT OF SYPHILIS.

Di-ortho-amino-thio-benzene ("Intramine").

At a meeting of the Dermatological Section of the Royal Society of Medicine on January 20th Mr. McDONAGH gave an account of a new drug he had devised for the treatment of syphilis. He had, he said, found by experiment that salvarsan did not attack the syphilitic organisms directly, but became attached to the lipid-globulin molecules of the serum, which, by the chemico-physical action of adsorption, killed the parasites. For this was necessary active oxygen, which was normally formed directly by peroxidases and indirectly by perhydriases. The arsenic in the salvarsan molecule, in the form of a hydroxide, acted as a peroxidase. Metals acted as peroxidases, and after experiments with aluminium and iron he had prepared drugs which acted better than arsenic and which were absolutely non-toxic. In early syphilis oxidation was more to the fore than reduction; the opposite was the case in late syphilis—therefore, he endeavoured to find out how the reductase system worked, and to make a drug which had the same action therein as aluminium, iron, and arsenic had in the oxidase system. He found that the perhydriase was a disulphide protein, and that sulphur (a non-metal) was the catalyst. Having prepared many sulphur compounds, he found that the di-ortho-amino-thio-benzene, to which he had applied the name "intramine," had the greatest therapeutic effect. It had proved to be in many respects more efficacious than salvarsan and to be absolutely non-toxic.

Mr. J. E. R. McDONAGH and Dr. H. SPENCE showed three cases of syphilis treated by "intramine":

1. Chronic ulcerative glossitis of twenty-five years' standing, which had resisted treatment with salvarsan, mercury, and iodides, and healed in a fortnight after one intramuscular injection of intramine.
2. Gummatous ulceration of genitals in a congenital syphilitic (male), aged 28. The ulcers healed with one injection of intramine and the general condition was greatly improved.
3. Recurrent papulo-ulcerative syphilide in a man aged 42, which healed in a week with one injection of intramine.

THE PILTDOWN SKULL.

THE question whether the later-found Piltdown canine tooth belongs to the Piltdown skull was raised in a paper read by Mr. W. COURTNEY LYNE, L.D.S., before the Odontological Section of the Royal Society of Medicine on January 24th. The canine tooth was not found in the mandible, but some time later near the spot where the original discovery was made. There is no vacant socket in the fragmentary mandible into which to fit this later-found tooth. It appeared, however, so reasonable to suppose that a canine tooth projecting above the general tooth level and of anthropoid character had once belonged to the fragment, that it was very generally accepted as genuine. Mr. Lyne's dissent from this view is founded on a critical examination, by means of x-ray pictures, of the pulp cavities of the two molars (the first and second permanent molars) *in situ* and of the later-found canine tooth. In all teeth of limited growth, whether temporary or permanent, a progressive diminution in size of the pulp cavity as age advances is brought about by concentric calcification; this affects the size of the root canal as well as that of the coronal pulp cavity. X-ray pictures show rather small pulp cavities and root canals in the Piltdown molars, and in the canine a large pulp cavity and root canal, so large that, assuming it to be a permanent tooth, it could not have belonged to an individual of greater age than 17. Arguing from the closed sagittal suture and from the ground-down condition of the molars the age of the Piltdown skull had been put at about 30. The molars and the canine, in Mr. Lyne's opinion, are incompatible in the same jaw. The apical foramen of the later-found canine is widely open, perhaps because a portion of the root is missing, and Mr. Lyne suggests that if it be really fractured and incomplete, the necessary addition would either raise the tooth beyond all reason or lengthen the root into the jaw till it would lie in the bone of the mandibular fragment, where in fact there is no trace of a socket to receive it. If, however, the later-found canine be, as Mr. Lyne supposes, a tem-

porary tooth, the open apex may be explained as the result of absorption. He argued that the very thin layer of enamel displayed, the loss of the tip of the tooth, the outwardly bent tendency of the root with apparent absorption beginning at the basal end of the root, along with the large size of the pulp, all pointed to a deciduous canine, and almost certainly a Primate one. The tooth is large; amongst Lemuridae in late Pleistocene times huge forms arose, for example, *Megaladapis insignis*, and it is thus quite conceivable that larger anthropoids than we have living now were in existence in late Pliocene or early Pleistocene times, and a somewhat large deciduous canine would not then be irrational.

In the discussion which followed, Dr. SMITH WOODWARD urged that it was far more probable that the remains belonged to one individual than that the cranial part, the mandible, and the canine tooth represented three absolutely new types, leaving their remains together in one small area; to which Mr. LYNE replied that he was only separating the canine tooth and so postulating two, not three, new types.

Professor KERTH said that because of the human shape of the glenoid cavity he had expected a large tooth, but not one so projecting as the later-found canine. The lower canine of anthropoids was faceted both by the upper canine and by the upper lateral; the later-found canine was faceted by the latter only. In the ape the canine was a cheek or side tooth; in man it belonged to the front series. The tooth might thus be an intermediate form and so compatible with the shape of the glenoid cavity. As showing that a large canine pulp cavity might be compatible with small molar pulp cavities he instanced the unexpected shapes of liver found in anthropoids. He thought the tooth belonged to the mandible.

Professor UNDERWOOD considered that Mr. Lyne had been very bold in coming to the conclusion that the tooth was that of a young individual by comparison of the pulp cavity with those of canine teeth of known age. He did not think the tooth temporary.

Professor ELLIOT SMITH explained that what he had said was that the age of the remains was about 30 when judged as modern man. It was probably actually younger. He had found it difficult, even in such recent skulls as those of ancient Egypt, to judge the age by closure of sutures or grinding down of teeth. There was often much grinding down in young skulls.

Mr. PYCRAFT pointed out that Mr. Lyne had made his comparison with microdont teeth, whereas the Piltdown teeth were macrodont, and should have been compared with macrodont teeth—for example, Melanesian.

Mr. HOPSON said that he had seen extreme grinding down in the temporary molars of a Neolithic child of 5 years of age, and thought that the slight tilting forward of the sockets of the third molar of the Piltdown mandible might be an indication of youth.

Mr. J. G. TURNER thought the slight forward tilt of the sockets of the third molar indicated a permanent condition of slight impaction of the tooth; he did not think it could be taken as a reliable guide to youth. In examining the grinding down of the teeth of old skulls, including ancient Egyptian, he had noted that the first permanent molar was rapidly ground flat, but that the second permanent molar was not worn at an equal rate, the tendency being to eat with the more forward teeth. The two molars (first and second permanent molars) of the Piltdown mandible were both worn flat, pointing to a considerably greater age than Mr. Lyne's 17 for the canine. The alveolar edges also of the Piltdown mandible were worn away. If this were truly an *ante-mortem* change it would only be due to a slow form of caries of the alveolar edge (pyorrhoæa alveolaris), which would have taken a good many years to reach the stage found. He had examined the pulp cavities of large numbers of human teeth, but had only twice, in molars, found such large pulp cavities and root canals in teeth of the age of 30 or so as shown by Mr. Lyne in the later-found canine. He thought, however, as Mr. Pycraft had said, the comparison should be remade with macrodont peoples.

Mr. LYNE, in his reply, expressed the opinion that no good answer had been made to the incompatibility of the large size of the pulp cavity of the canine, especially of the lower third of the root, with the size of the molar pulp cavities.

Rebueluz.

DISEASES AND THE DUCTLESS GLANDS.

As everybody knows, the ductless and endocrine glands have received a vast amount of attention from physiologists, pathologists, and clinicians during the last two decades; the literature of the subject has become enormous. From the point of view of the experimental physiology and pathology of the subject, the massive handbook by Biedl contains most of what is known, and for the general reader the little book by Sir E. A. Schäfer, reviewed in the *BRITISH MEDICAL JOURNAL* of June 5th, 1915, p. 981, contains a satisfactory *précis* of our knowledge. From the clinical point of view, a full and very valuable account of the ductless glands was published in 1913 by Dr. FALTA of Vienna, and this has recently been translated by Dr. MEYERS.¹ The book is founded on Dr. Falta's own observations, made at various Viennese clinics. Its contents are divided into fourteen chapters. After a well-written introduction, in which the complexity and uncertainties in which the single and combined actions of the secretions of the ductless glands are involved are well set out, the rest of the book is given to clinical accounts of disturbances of each endocrine gland separately. The thyroid, parathyroid, thymus, pituitary, pineal, suprarenal, lymphatic, sexual, and pancreatic glands are all discussed from this point of view. Special chapters are given to pluriglandular diseases and to vegetative disturbances not directly dependent on disorder of the ductless glands, but yet the cause of dwarfism, infantilism, mongolism, and chondrodystrophy; while the last chapter goes thoroughly into the question of the different forms of obesity. At the end of the book 70 pages are devoted to references to the literature of the subject; throughout the text Dr. Falta makes very full use of the writings of others to illustrate his meaning. The volume contains countless points of interest and well-balanced discussions—for example, his analysis of the signs and symptoms of chlorosis leads the author to attribute that disease to an exhaustion of the ductless glands generally, brought about by abnormal or precipitate ovulation, and to suggest that the disease might be treated by a very cautious irradiation of the ovaries with α rays. The translator has done his work in a painstaking manner, although his rendering not infrequently sticks too closely to the German original. This may be illustrated by a sentence from the chapter on the diseases of the thymus gland: "Stöhr regards the origin of the thymus lymphocytes as due to a partition of the epithelial pictures" (p. 223). The translation has been brought up to date by editorial addenda. There are many misprints in the names of the authors quoted.

ANATOMY.

IN his massive textbook of *Applied Anatomy*² Professor G. G. DAVIS describes at great length the construction of the human body considered in relation to its functions, diseases, and injuries. The first edition came out five years ago; the third, now before us, preserves the characters of the first, with comparatively slight corrections and additions. For all its size, the book is not a systematic treatise on anatomy, but is an explanatory and utilitarian work for the medical student. Naturally enough, it deals mainly with the applications of anatomy to surgery; the redistributions of anatomical structures caused by fractures and dislocations are dealt with very thoroughly, and so are the special anatomical points that it is thought should be in the mind of the operating surgeon when he is at work. Many hundreds of excellent illustrations of dissections made to illuminate the points at issue are included, and, speaking generally, could hardly be improved upon. From the medical point of view the book would appear to be less complete. In the account of the lungs, for example, no mention is made of the differences on percussion and palpation normally met
